Acknowledgments

The RCD would like to thank the many landowners who made this survey effort possible. In addition this effort was made possible by the contributions of the following people:

Survey Crews:
Gary Black – Siskiyou RCD
Crystal Bowman– Siskiyou RCD
John Bowman– Siskiyou RCD
Amaria Crocoll – Americorps
Bobbie DiMonte – NOAA
Bryan Drew - USFS
Mark Elfgen - CDFG
Donald Flickinger – NOAA
Ed Gozzarino – Volunteer
Jim Kilgore – USFS
James Lee – FruitGrowers Supply Co.
Shawn Lenihan - Volunteer
Beth Marder– Siskiyou RCD
Sue Maurer – Volunteer
Christan Norman - Americorps
Jay Phelps - Volunteer
Mark Pisano – CDFG
Danielle Quigley - Siskiyou RCD
Jennifer Silveira - USFWS
Jim Whelan – CDFG
Erich Yokel – Siskiyou RCD

The following people should be acknowledged for their contribution to report writing.

Gary Black
Erich Yokel
Jennifer Silveira

Cooperators include: local landowners, California Dept. of Fish and Game (CDFG), United States Forest Service (USFS), United States Fish and Wildlife Service (USFWS), National Oceanic and Atmospheric Administration (NOAA), Americorps Watershed Stewards Project, and the Siskiyou RCD.

Abstract

Adult coho spawning ground surveys were completed in a total of 47.20 stream miles (44.45 miles of tributaries, and 2.75 miles of mainstem) in the Scott River Watershed. Live coho salmon were spotted in the Scott River as early as October 22nd, 2004, with radiotag verification on October 26th, 2004. The survey season was November 16th, 2004– January 14th, 2005. Total counts for the season were 960 redds, 569 Carcasses, and 1577 live fish counts (although some live fish were likely counted twice during weekly surveys).

Adult coho spawning ground and carcass surveys were completed in the Scott River Mainstem and the following tributaries: East Fork Scott, Grouse Creek, Kangaroo Creek, Rail Creek, South Fork Scott, Sugar Creek, French Creek, Miners Creek, Paynes Creek (trib to French), Etna Creek, Patterson Creek, Kidder Creek, Shackleford, and Mill Creek (trib to Shackleford), Canyon Creek, Boulder Creek, Kelsey Creek and Kelsey spawning channel, Middle Creek, Tompkins Creek, and Mill Creek (Scott Bar). Spot surveys were completed at the mouths of Fox Creek, Boulder Creek, tributaries to the South Fork Scott.

Exceptional survey conditions allowed for the observation of coho salmon in the river, on redds, and as carcasses. This allowed for proper ID of fish, migration timing, and spawning. Several factors contributed to exceptional survey conditions during the survey period. Prior to December, flows were stable and visibility was excellent. However, fish passage was limited in many tributaries due to seasonal flow barriers at the mouths of the tributaries. Heavy rains during the first week of December (Dec 6th – 8th) brought fish into the system and reconnected most of the perennial streams, providing access for spawning salmon. Good visibility was restored shortly thereafter.

Adult coho spawning was well distributed throughout the sub-basin, with spawning occurring in many of the tributaries investigated. The only tributaries which did not show coho spawning activity were: Middle Creek, Fox Creek, Boulder Creek (Scott), Boulder Creek (S. Fork) , and Paynes Creek. The heaviest spawning activity observed was in the lower sections of Patterson, Shackleford-Mill, French-Miners, Kidder, Etna Creek, and Sugar Creek.

Population estimates were developed for selected reaches in French, Miners, Shackleford, and Mill Creek, using mark and recapture techniques. The Peterson and Schaefer estimate were utilized. Peterson estimates were as follows: Middle French 181 adults (Confidence Interval = 156-209), Miners = 221 (193-252), Lower Shackleford = 201 (174-230), and Lower Mill = 337 (299-374). Schaefer estimates were: Middle French 163 adults (confidence interval = 140-190), Miners = 133 (112-157), Lower Shackleford = 110 (91-133), and Lower Mill = 307 (274-343).

Introduction

Coho salmon (*Oncorhynchus kisutch*) in the Klamath River Basin, the Southern Oregon-Northern California Coast ESU, were listed as threatened by the National Marine Fisheries Service in 1997. In 2001 the State of California began considering a listing of the species as threatened, and in August of 2004 the California Fish and Game Commission acted to add the coho to the list of endangered and threatened species. The listing became effective March 30th, 2005.

Adult coho spawning ground surveys have been performed cooperatively in the Scott River Watershed annually since the winter of 2001-2002. Scott River adult coho spawning ground surveys began in December 2001 as a cooperative effort between local landowners, agencies, and concerned volunteers. The purpose of the 2001-2002 survey effort was to document where adult coho salmon held and spawned throughout the basin, as well as establish index reaches for future monitoring. This survey provided invaluable information on tributaries used for adult coho spawning, as well as insight into the timing of the Scott River Adult Coho run. In addition, some of the first genetic samples were collected on Scott River coho, providing information on the relationship of Scott River coho to other coho in the Klamath Basin.

These annual spawning ground surveys are one part of the ongoing effort by the Scott River Watershed Council (SRWC) and Siskiyou RCD (RCD) to understand the life history of coho salmon in the Scott River Basin. Additional planned studies include summer juvenile habitat utilization surveys, and juvenile outmigrant trapping on tributaries.

Spawning ground and carcass surveys in the Scott River Watershed aim to address the following goals:

- Determine and map the distribution and upper extent of coho spawning.
- Determine the timing of adult coho migration and spawning.
- Estimate populations utilizing different tributaries.
- Sample biological parameters.
- Observe spawning habitats utilized by coho salmon.

During the surveys of 2001-2002, index reaches were established to document trends in coho spawning, (Canyon Cr., Lower Masterson, Mid French Cr., Lower Sugar Cr., Lower S. Fork, and Upper S. Fork). These index reaches, and other reaches, have been surveyed annually since 2001. However, these index reaches are not fully representative of the distribution of coho throughout the basin, or the variation in stream habitat present throughout the basin. Various factors in 2001 contributed to the survey effort being incomplete: lack of time to coordinate access, a small available budget, lack of available trained personnel during key spawning periods, and adverse flow conditions (ie. multiple storm runoff events). In addition, during the early fall of 2001 flow conditions were not ideal for adult migration and distribution. The summer of 2001 was a drought year, with large stretches of the Scott River Mainstem and alluvial tributaries drying up.

Connectivity was not restored to the main Scott River until November 22nd, 2001, and significantly later for tributaries. This likely led to spawning in non-ideal conditions, and prevented spawning in some of the more likely tributaries (ie. Patterson Creek).

Therefore, in order to fully document the extent of coho spawning distribution and timing, the survey effort has been expanded significantly since 2001. The subsequent surveys of 2002-2003 and 2003-2004 had wider spatial distribution of reaches, and covered more mileage. However, the coho runs during those years were too small to adequately document the full distribution and timing of the coho spawning.

The 2004-2005 adult coho run (return run from the 2001-2002 brood year) was expected to be a large run. Therefore, extra effort was made to document the timing and full extent of spawning distribution in the Scott River. Many of the reaches previously established were significantly expanded in the effort to survey as much mileage as possible. In addition, population estimates through mark and recapture efforts were planned for selected tributaries, and data on habitat specific feature collected.

This extensive survey of adult spawning distribution and habitat utilization allows for the identification of areas of essential habitat. This will allow for the development of more effective, targeted restoration measures. In addition, it provides information on areas of habitat that will be fully seeded by juveniles for the next year. This will allow for the selection of reaches for further habitat utilization studies (winter and summer habitat).

Exceptional survey conditions during the winter of 2004-2005 allowed for the observation of coho salmon in the river, on redds, and as carcasses. This allowed for proper ID of fish, migration timing, and spawning. Several factors contributed to exceptional survey conditions during the survey period. Prior to December, flows were stable and visibility was excellent. However, fish passage was limited in many tributaries due to seasonal flow barriers at the mouths. Heavy rains during the first week of December (Dec 6th – 8th) brought fish into the system and reconnected most of the perennial streams, providing access for spawning salmon. Flows receded significantly following the rains. By December 12th flows were down, streams were safe to wade, and there was excellent visibility for both redd and fish identification. From the end of the rains on Dec 8th, until the end of the survey period (Jan 14th) flows were stable with no significant rain events to cause turbidity or obscure visibility.

Project Objectives:

1) Document the presence of coho salmon in streams within the historic range of distribution and in new tributaries not previously documented within the Scott River system. Survey "index reaches", as delineated in the 2001-2002 survey, once per week once the spawning begins (December 1, 2004-January 31, 2005), or as determined by run timing.

2) Document the distribution and upper extent of spawning in each of the tributaries where adult coho salmon were observed.

3) Determine the run timing and duration of adult coho salmon spawning in the Scott River.

4) Collect two sets of tissue samples for DNA analysis to understand the genetic relationship of the Scott River coho salmon to other stocks and collect two sets of scale samples to understand the life history of the Scott River coho salmon. One set of tissue and scale samples will go to NOAA Fisheries and one to CDFG.

5) Determine additional site specific information as they relate to spawning: Redd composition, substrate composition, temperature and stream gradient.

6.) Population Estimates: Complete mark and recapture in Shackleford-Mill and French-Miners Creek.

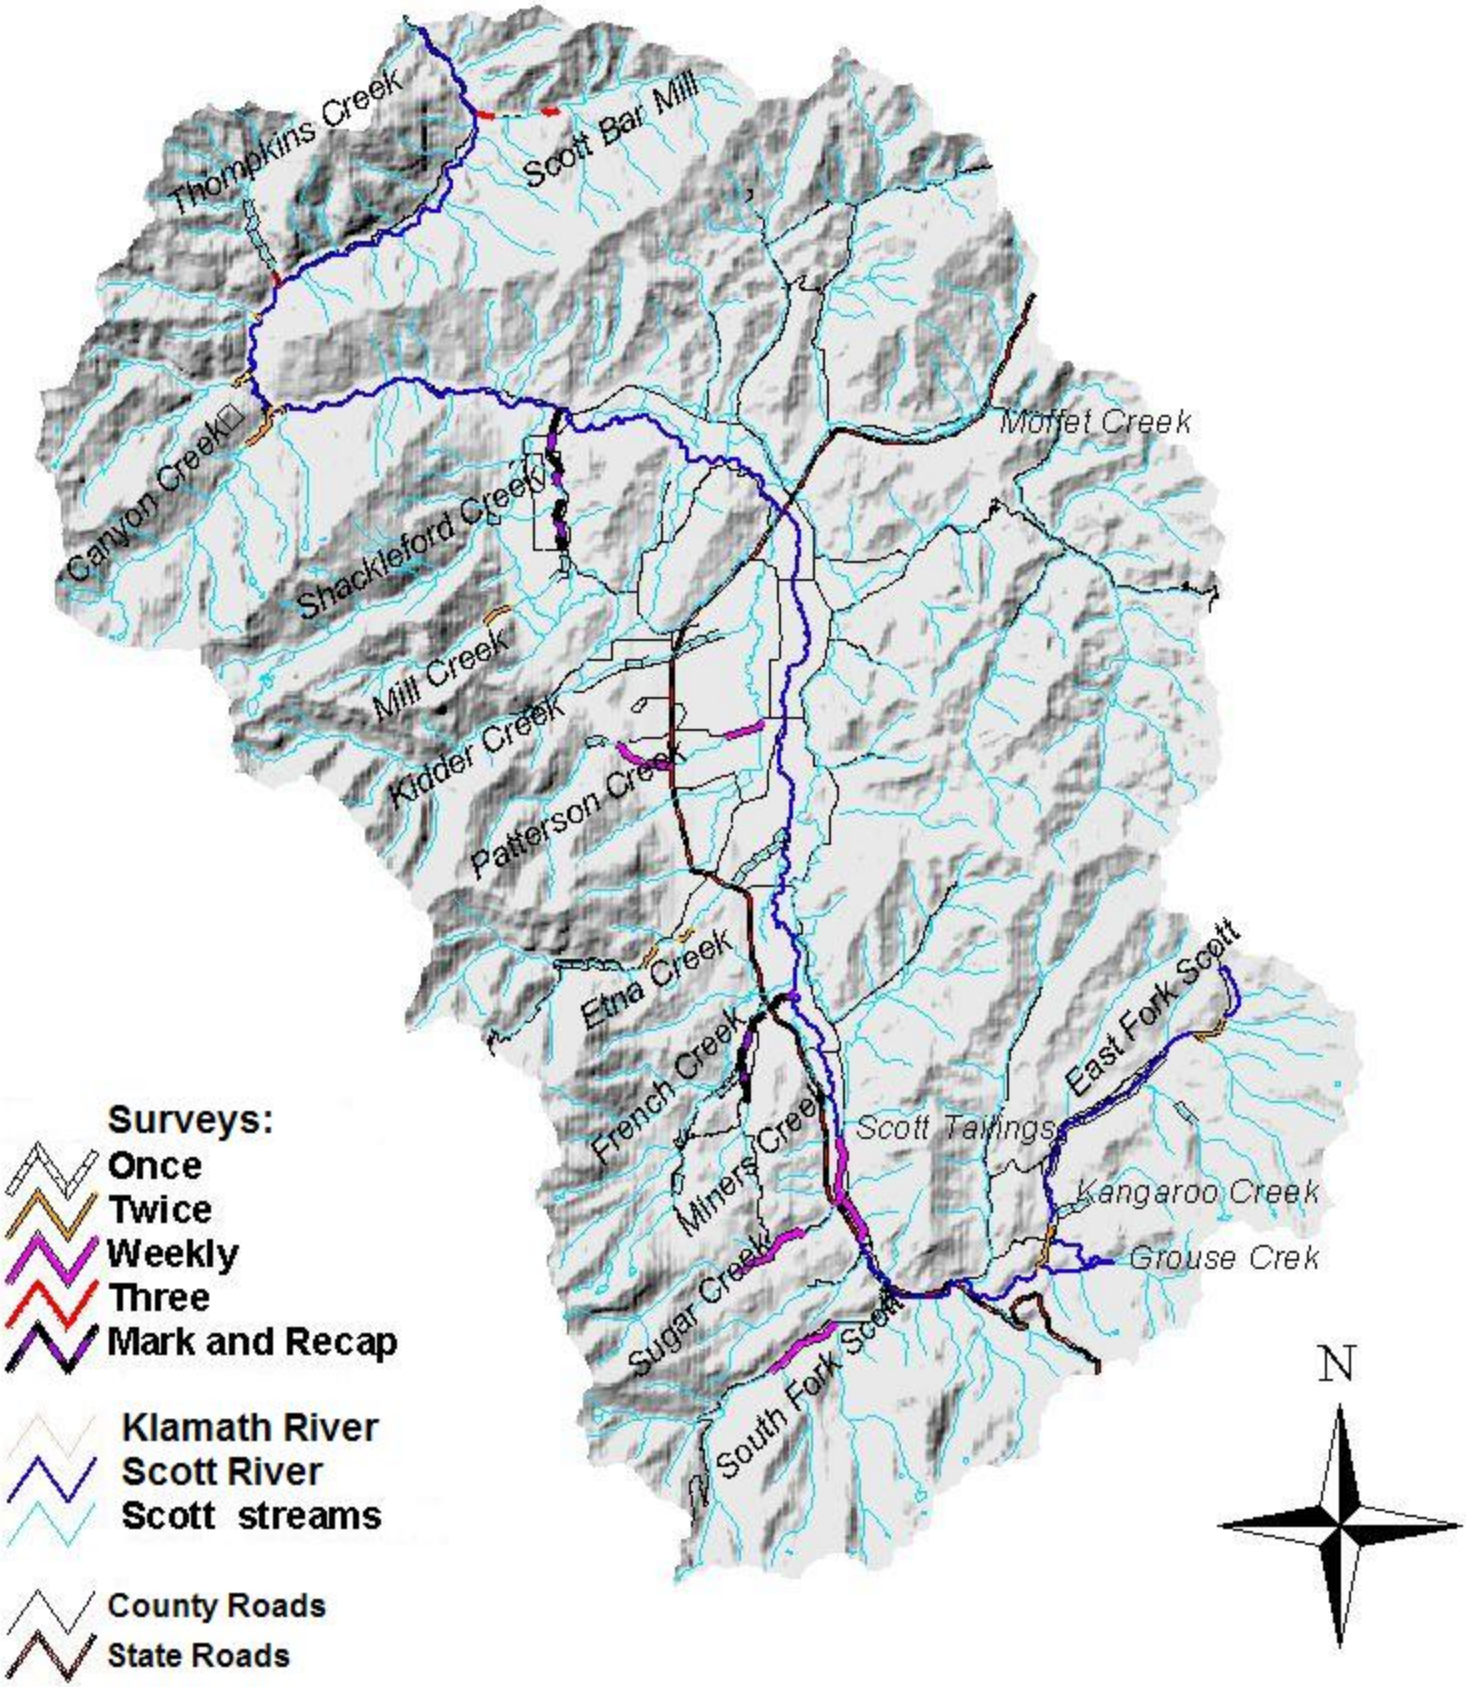
Reach Locations



Methods

Project Location
This data collection effort took place in the Scott River sub-basin of the Klamath River Basin. The Scott River is located in Siskiyou County, CA. The Scott River drains approximately 813.5 square miles. See Map #1.

Survey Locations
Adult coho spawning ground and carcass surveys were completed in the Scott River mainstem and the following tributaries: East Fork Scott, Rail Cr, Grouse Cr., Kangaroo Cr., South Fork Scott, Sugar Creek, French Creek, Miners Creek, Paynes Creek (tributary to French), Etna Creek, Patterson Creek, Kidder Creek, Shackleford, Mill Creek (tributary to Shackleford), Emigrant Creek, Canyon Creek, Boulder Creek (Scott Canyon), Kelsey Creek and spawning channel, Middle Creek, Tompkins Creek, and Mill Creek (Scott Bar). Surveys were completed in all streams surveyed in the 2001-2002 season, with the exception of Wooliver Creek, and streams which did not regain connectivity during the survey season (Nov 16th – Jan 14th). Effort was made to survey all stream reaches from 2001, where access and connectivity allowed. See Map #2 for locations of 2004-2005 reaches.

The following streams were surveyed in 2001, but not surveyed this season due to a lack of connectivity throughout the season; Moffet Creek, McAdams Creek, Rattlesnake Creek. An estimated 92 miles of tributary are available for coho spawning. A total of 47.2 miles was surveyed at least once during the season, including 2.75 miles of mainstem Scott River and 44.45 miles of tributary.

Survey Schedule
Mark and recapture reaches and other important reaches were surveyed weekly. Index reaches were surveyed weekly except for the following: Canyon Creek was surveyed three times, Lower Masterson was surveyed twice, and Lower South Fork was surveyed once. Other streams were surveyed one to three times, depending on access and crew availability. A total of 44.45 miles of tributary were surveyed (48.4 % of available). However, the lack of connectivity of Moffet-McAdams, and other tributaries reduced the potential available habitat by ~40 miles (according to Maurer 2003). During the survey period 16.0 miles of tributary were surveyed weekly for an eight week period. An additional 31.2 miles of tributary were surveyed at least once.

See Table I, Survey Reach Descriptions, for a description of each reach, and survey frequency.

Table I. Survey Reach Description

Watershed	Reach Description	Begin Mile	End Mile	Survey Schedule	Survey Crew	Total Miles
Mill Cr. (Scott Bar

Crew training

Crew training was organized by California Dept. of Fish and Game (CDFG) and the Siskiyou RCD. Training was held on November 17th at the Siskiyou RCD office. Training included: Fish ID, tissue and scale sampling techniques, identification of marks and tags that have been applied throughout the Klamath Basin, GPS use and naming conventions, data sheets, and redd identification. See Appendix A, Training Materials.

All Siskiyou RCD field crew members had participated in the Adult Chinook Spawning Ground Surveys (CDFG) for several years, and had participated in the Scott River Adult Coho Spawning Ground surveys in previous years.

Table II. Training Participant List.

Name		Affiliation
Crystal	Bowman	Siskiyou RCD

Spawning Ground and Carcass Surveys

Stream surveys were completed by a two person field crew. A stream survey is completed by walking instream, or on the bank (to avoid disturbing redds) beginning upstream and moving downstream. Crew members walk on opposite sides of the stream, looking for redds and fish. The location of any fish, redd, or carcasses was recorded by GPS, and noted on the data sheet. In addition, flagging was hung at redds to mark for the next survey crew, preventing double counting of redds. Carcasses are processed, then chopped to prevent double counting. Tissue and scale samples were taken from a subset of carcasses, and the species, sex, fork length, and any marking recorded on the data sheet. One member of each crew had a State of California Scientific Collection Permit, or went on the survey with a CDFG employee.

During redd surveys, the following data was collected on redds, if it did not disturb the spawning fish: redd length, width, pott depth, and substrate composition. Substrate composition categories are: Sand (<.2 cm), small gravel (.2-5 cm), large gravel (6-9 cm), small cobble (10-13 cm), and large cobble (> 13 cm).

See Appendix A for sample datasheets.

Tissue and Scale Sample Collection

Two sets of tissue and scale samples were taken from a subset of carcasses retrieved. During the first part of the survey season (November 16th – December 15th) scale and tissue samples were taken from all carcasses. After that point in the season, carcasses were so abundant that the protocol was changed to collect five (5) samples per reach per survey. This protocol change was initiated to ensure that surveys could be completed in one day, which was especially important in mark and recapture reaches. In addition, NOAA fisheries indicated that 50-75 sets of genetic samples would be sufficient for their analysis.

Tissue samples were collected by clipping a one cm^2 piece of operculum tissue. Samples were placed in absorptive paper, and placed into labeled envelopes. Scale samples were collected below the dorsal fin, but above the lateral line. Samples were collected by scraping with a knife blade in the direction from head to tail. Scale samples were placed in a labeled scale envelope. Both sets of samples were either picked up by, or hand delivered to Mark Pisano (CDFG).

GPS Data Collection

Hand-held Global Positioning System (GPS) units were used to record the location of the beginning and end of each survey reach, and location of each carcass, redd, and live fish identified. However, beginning December 15th, a modification was made to the protocol due to the large number of spawning fish. At this point all redds continued to be marked, with the exception of some reaches with heavy use. In this case redds were grouped if found within 10 meters of each other. Only carcasses which were sampled were marked, and live fish sighting were grouped. The exception to this was if the fish or carcass was found in a unique location, or beyond the upper extent previously observed. In that case a GPS point was taken.

GPS waypoints were assigned an ID based on a stream code, sequential number, and a letter code denoting carcass (C), redd (R), or live fish (F).

Ex.) F C 0 4 C = French Creek # 4 Carcass

In addition, the GPS coordinates in Lat/Long were recorded on the field data sheet, along with the ID code assigned to that data point. See Appendix A for further detail on naming conventions.

Fish ID and Mark Identification

Fish ID

Positive identification of coho salmon was a crucial step in conducting the spawning ground surveys, and the collection of the tissue and scale samples. Mark Pisano, Biologist-CDFG, provided hatchery carcasses of all three species (coho, Chinook, and steelhead) present in the Scott River Watershed, to ensure that the crew was fully aware of key identifying features.

The following characteristics are used to identify coho salmon:

Gums: Coho salmon have white gums at the base of the teeth only; typically the rest of the gum is gray.

Spots: These spots are black in color and can vary from circular to irregularly shaped spots. Both sexes have spots on the back, dorsal fin, and upper lobe of the caudal fin, with no spots on the lower lobe.

Color: Many coho salmon, both male and female, can exhibit extremely brilliant pink to red coloration of the lower 2/3 of the body.

Kype: Both males and females can have a fairly pronounced kype

Nares: Nares are enlarged and white in coloration. This characteristic is useful in identification of live fish due to the visibility.

Caudal Peduncle: the caudal peduncle is thicker than that of a Chinook. This is most noticeable when picking up a carcass, making it difficult to hold in one hand.

Anal Fin: The anal fin of coho salmon have 12-17 rays, and the outermost rays are longer than the inner rays, which is not the case with Chinook or steelhead.

Sex: Males generally are larger, have larger hooked kypes, and brilliant pink to red coloration. To verify the sex the anal opening was squeezed to determine the presence of milt (male) or eggs (female).

Origin: Hatchery fish are identified by either the lack of an adipose fin, or by a maxillary clip. (Right maxillary clip = Trinity River Hatchery, Left maxillary clip = Iron Gate Hatchery) Adipose clipped fish have the snout removed and submitted to CDFG for coded-wire tag recovery.

Mark Identification
During this season, many tags were applied to Klamath River adult coho by various agencies throughout the Klamath Basin.

California Department of Fish and Game
The California Dept of Fish and Game (CDFG) applied floy tags on the right side of approximately 336 unmarked coho returning to Iron Gate Hatchery. This tagging was conducted from October 29th – December 16th, 2004. In addition, the United States Fish and Wildlife Service (USFWS) tagged 40 Iron Gate Hatchery coho with radio transmitters and spaghetti tags. These fish were then given an anterior caudal clip and returned to the Klamath River mainstem below Iron Gate Hatchery (Mark Hampton-CDFG Pers. Communication).

Karuk Tribe
The Karuk Tribe applied radio tags to eighteen (18) coho at Ishi Pishi Falls (near Somes Bar), between October 12th and 21st. Radio tagged fish were marked with spaghetti tags, and each fish had a unique radio signal. A total of nine (9) of these tagged fish entered the Scott River. The first tagged fish entered the Scott River on October 26th, 2004.

All field crew were notified to look for these tags, and trained in the identification of tags.

Mark and Recapture
French-Miners Creek and Shackleford-Mill were selected for an pilot effort to conduct mark and recapture surveys in the same method as that completed by CDFG during the annual Fall Chinook Spawning Ground Surveys. These tributaries were selected based on known habitat quality, expected large runs, and the nearly full coverage granted by landowners. Estimates were completed on a reach basis, rather than tributary basis because different flow conditions, instream conditions, and predation rates contributed to different efficiencies.

Individually numbered tags were applied to each fresh carcass found during each survey. Tags are applied to the inside lower right jaw. The tag number applied was recorded on the field data sheet. All carcasses were inspected for tags upon retrieval. Recaptured carcasses were recorded on the field data sheet. This data was used to generate both Peterson and Schaefer population estimates for individual reaches. See Appendix B – Redd and Carcass Information and Appendix C – Population Estimates.

Temperature Data
Stream temperature data was collected in Sugar Creek, French Creek, Mill Creek, Shackleford-Mill, and the South Fork of the Scott River during the survey period. Data collection was done using Onset HoboTemps continuous dataloggers. Data was collected at hourly intervals. See Appendix D - Stream Temperature Data.

Results

Run Timing and Duration of Coho Spawning

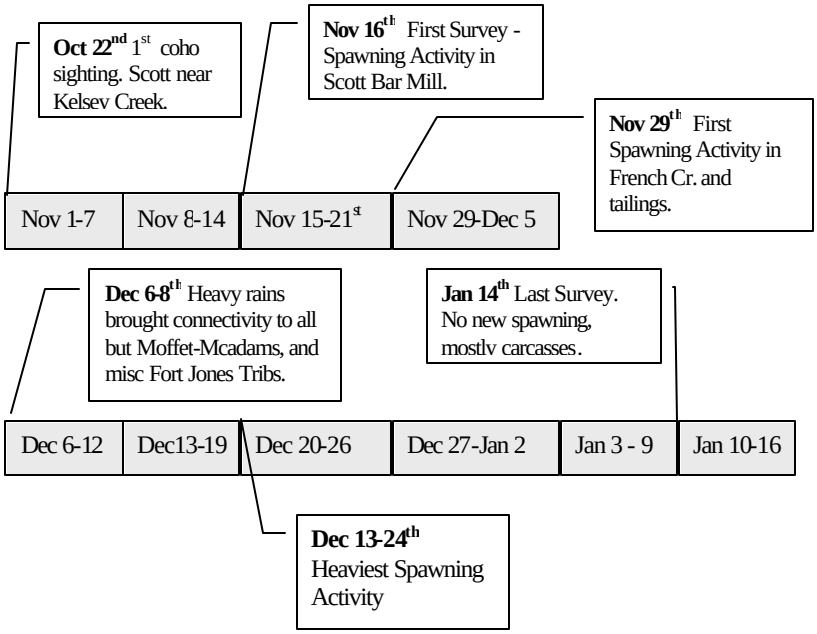

Figure I. Adult coho spawning run timing in the Scott River – 2004.

Initial Coho Sightings

The first sighting of live coho adults in the Scott River was October 22nd, 2004, in the Scott River near Kelsey Creek. (California Dept. of Fish and Game – Fall Chinook Spawning Ground Surveys). Coho radiotagged by the Karuk tribe entered the Scott River on October 26th, and many fish were observed holding in the Scott River canyon between George Allen Gulch (RM 7.8) and Pat Ford (RM 4.9) until the rains in early December. One radiotagged fish was documented above the mouth of Sugar Creek (RM 54) on December 5th, and likely spawned there. Following the rains of December 6th – 8th, most of the major tributaries to the Scott River regained connectivity. During this period, coho dispersed throughout the basin. Radiotagged coho were known to have entered French Creek, Shackleford-Mill, Mill Creek (Scott Bar) and Patterson Creek, following the rains of December 6th – 8th.

Initial Spawning Period
The first spawning activity was documented in Scott Bar Mill Creek on November 16th, 2004 with spawning documented in French Creek, and the Scott tailings (~RM 55) by Nov 29th. By December 3rd fish had been spotted as far upstream in the system as the East Fork near Grouse Creek (61.4 miles from the mouth of the Scott). During this period seasonal low flow barriers prevented access to Shackleford-Mill, Patterson, Etna, Kidder, and Moffet-McAdams Creek, Rattlesnake, and Indian Cr. In addition, low flows combined with beaver activity prevented access into Sugar Creek, and hindered access to French Creek.

Connectivity Restored to Valley Tributaries
Heavy rainfall from December 6th-8th restored connectivity to Shackleford-Mill, Kidder, Patterson, and Etna Creek, and provided better access to Sugar and French Creek. However, connectivity did not return to Moffet-McAdams, Rattlesnake, or Indian Creek during the survey period (November 16th – January 14th). The week following the rains (December 13th-19th) coho were seen actively spawning in the following tributaries: French-Miners, Shackleford-Mill, Sugar Creek, South Fork, East Fork, Patterson Creek, Kelsey Creek and Kelsey spawning channel, and Scott Bar Mill Creek. The peak spawning period occurred between December 13th and 24th.

The fish died off relatively close together, directly following the peak spawning period. Large numbers of carcasses were found beginning on December 20th. Little new redd activity or fresh fish were observed after early January.

Redd Survey Results
The survey season lasted from November 16th – January 14th, 2005. During this period a total of 960 redds, 569 carcasses, and 1577 live fish were identified. However, in reaches surveyed weekly (French-Miners Cr., Shackleford-Mill, Sugar Creek), some fish were likely double counted. This is because fish generally spawn for several days, and could still be on the redd during the next survey.

In addition, due to landowner concerns, only redd counts were completed in Middle Mill and Emmigrant Creek. This affected the live count for Shackleford-Mill. Finally, some reaches were not surveyed until the peak of activity had passed, and many fish were dead already (Lower Kidder, Lower Patterson, Lower Etna). Table III documents the redds, carcasses and live fish identified during the survey season. Some reaches designated in 2001 were expanded in 2004. To allow comparison with 2001, Table III shows redd counts for these shorter 2001 reaches separately. However, the live fish and carcass data could not be extracted from the longer 2004 reaches, so they are included with the 2004 reaches' data.

* = New reach in 2004

Shaded reaches surveyed in 2001-2002

Flow Conditions

Survey conditions were ideal for both redd and fish identification. During the early period of the survey (November 16th – Dec 8th) flows were slightly above summer baseflow conditions. These low, clear flows made redds extremely clear, and low water contributed to ease of fish ID. Following the rains of December 6 – 8th, flows stabilized quickly, and turbidity cleared up. From the end of the rains on December 8th, until the end of the survey period, flows were stable, and good visibility was restored.

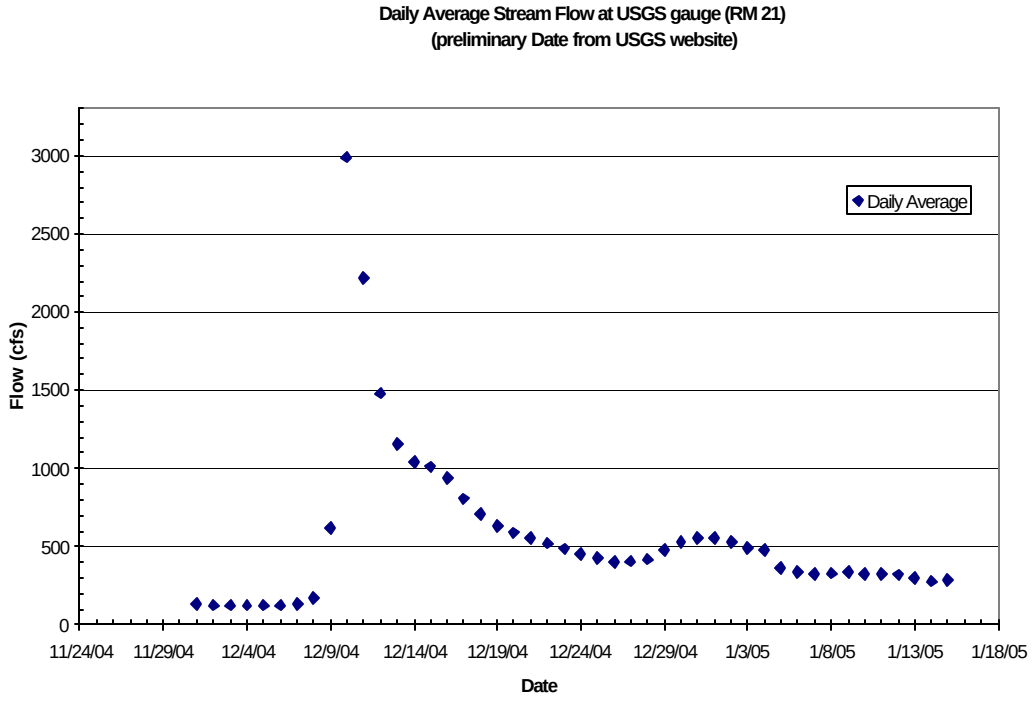

Figure II. Streamflow at USGS gauge during survey period.

(Note: USGS data is preliminary only.)

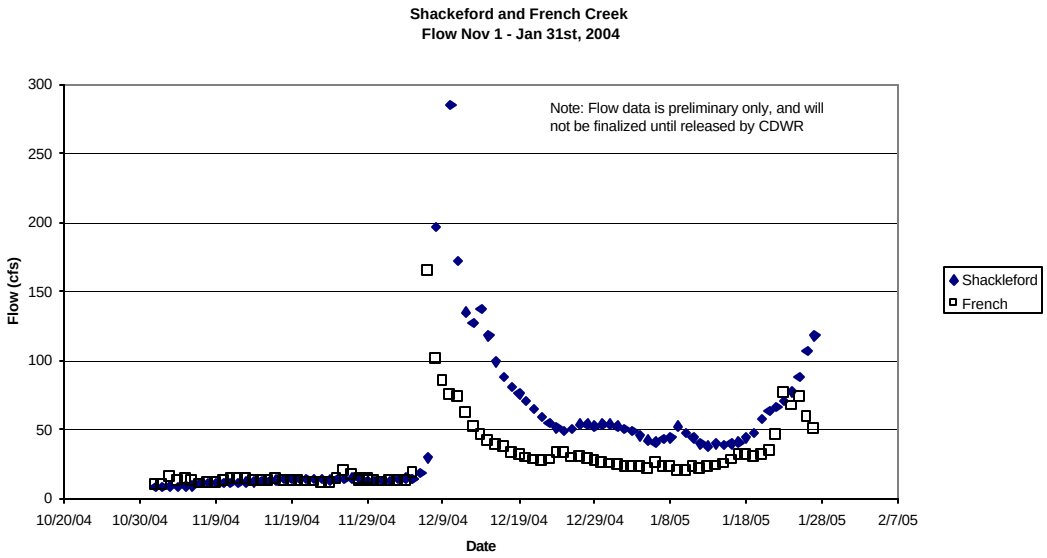

Figure III. Flow Data for Shackleford and French Creek.

(Note: this is preliminary estimated data only, and not final until released by the California Department of Water Resources

Comparison to 2001-2002 Survey Results (Same Brood Year of Coho)

Survey results for the 2004-2005 survey season are not directly comparable to those of 2001-2002 for the following reasons: Due to the short time frame, volunteer nature, and flow conditions experienced during the 2001-2002 surveys, most reaches were surveyed at most 3 times, including the index reaches. Flow conditions varied greatly during the 2001-2002 survey period, with multiple winter storms in December making the stream impossible to survey. In contrast, during the surveys of 2004-2005. flow conditions were stable throughout the survey period, with the exception of the period directly following the rains of Dec 6-8th. This led to nearly ideal survey conditions, and the RCD had sufficient funding, access, and time to survey many reaches on a regular basis.

A comparison of just the reaches surveyed in both 2001 and 2004 shows an increase in redds from 206 in 2001 to 458 in 2004. (See Table IV.)

Observations from Spawning Ground Surveys

Positive Identification of Fish

In all reaches surveyed weekly, identification of fish and redds has a high degree of confidence. In reaches surveyed weekly, redds with fish identified on them ranged from 62-84% of total redds. In many cases, a redd identified without a fish one week would have a coho on it the next week.

In addition; the Chinook run had ended well before coho entered the valley tributaries. (Nov 22nd survey of mainstem near Horn Lane found no Chinook activity). During the Fall Chinook spawning period, most of the tributaries were not connected. A total of 569

coho carcasses and one (1) steelhead carcass, and zero (0) Chinook carcasses were found during the survey period. This supports that the observed spawning was coho rather than Chinook or steelhead.

Finally, coho spawning observed was in markedly different habitat than that generally utilized by Chinook salmon. In general, coho spawning was observed in side channels with a component of riparian cover, or in main channel with overhead cover. The heaviest spawning occurred in low gradient reaches, with superimposition of redds occurring in many locations.

Factors which contributed to redds without a positive fish ID are: reaches surveyed after or at the tail end of the peak spawning activity (lower Kidder, lower Etna, lower Kangaroo, and second surveys in Tompkins Creek and lower Scott Bar Mill), the tendency of the fish to spook and return to redds later, and the availability of suitable habitat for fish to take cover in. This is especially true in Patterson, Miners, and French, where many pools with complex cover elements exist.

Redd Observations

During the survey period, many reaches had observations of multiple fish on a single redd (as many as six fish in some cases). This occurred most frequently in lower Sugar Creek, Miners Creek, lower Patterson, lower Shackleford, and lower Mill Creek (Shackleford). In addition, superimposition of redds occurred in many reaches. This occurred more frequently in the reaches which showed heavy spawning activity.

In the more heavily utilized stream reaches, spawning occurred in side-channels (lower Patterson, mid-French, Miners, lower Shackleford.) It was observed during the cold period in early January that some of these side channels might experience surface dewatering of redds, as well as surface freezing. It is unknown what affect this might have on eggs buried 6-10 inches below the surface.

Extent of Coho Spawning Distribution

During the survey season effort was made to survey all reaches established in 2001, index and others, to compare the return run from that brood year. In addition, effort was made to survey as high in each tributary as coho spawning might occur, in order to document the upper extent of spawning. Survey efforts in Shackleford-Mill, Sugar Creek, Patterson Creek, and French Creek, were extensive, and covered a great deal of available habitat. Surveys in the East Fork, Miners Creek, and Kidder Creek were limited by access, and do still do not fully represent the available spawning habitat.

The spawning distribution proved to be more extensive than in 2001. Spawning was well distributed in 2004, with spawning found higher in some tributaries than previously observed (Upper Mill Creek, Upper East Fork, Upper Sugar Creek). In addition, spawning was observed in stream reaches not previously observed (Upper Mill Creek, Canyon Creek, Lower Kidder Creek, Lower Tompkins), as well as in newly documented reaches established in 2004 (Lower Etna, Lower Patterson, Middle Patterson, extended

tailings reach). See Table IV. For a visual representation of the 2004-2005 spawning distribution, see Map #3.

No spawning was documented in Grouse Creek, Middle Creek, Boulder Creek (Scott Canyon), lower Boulder Creek (S. Fork) or Paynes Creek, or the mouth of Fox or Boulder Cr. No spawning was observed in the survey reach on Rail Creek. Coho were observed holding and spawning in the lower 200 feet of Rail Creek. (G. Black pers. comm.) However, no formal survey was completed in this section of Rail Creek.

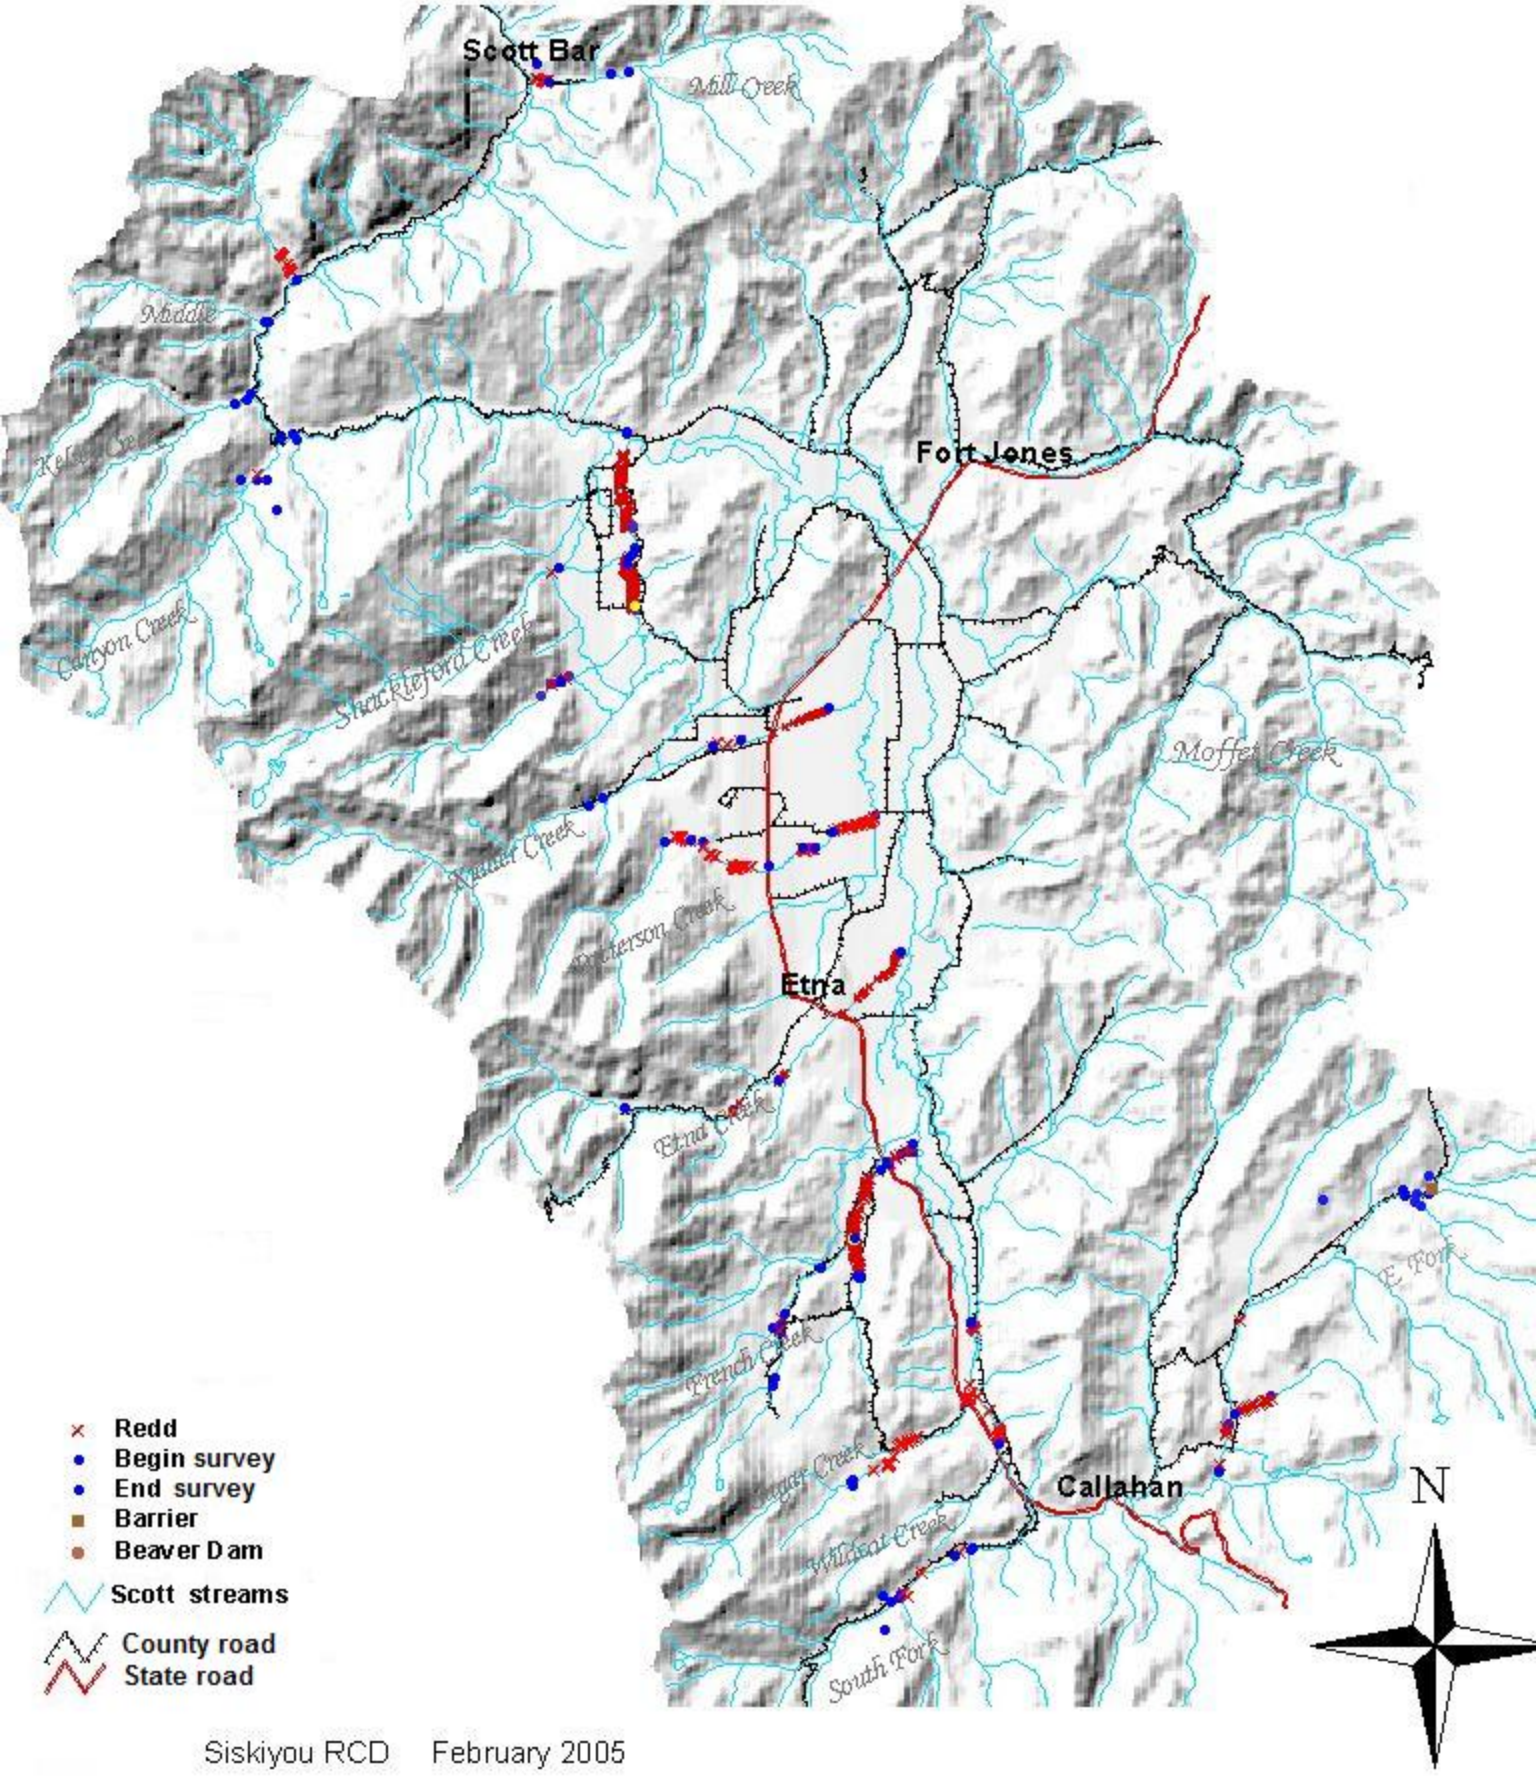
Scott River Adult Coho Survey 2004-2005
Map # 3
Redd Distribution



Siskiyou RCD February 2005

Tissue and Scale Sample Collection

A total of 569 coho carcasses were found in the Scott River watershed. Of those identified, 315 (55.3 %) were female, (43.5%) were male, and six were of unknown sex due to predation. The average fork length for female carcasses was 67.6 cm, with a range of 54-81 cm. The average fork length for males was 70.3 cm, with a range of 42-81cm. One jack coho carcass was identified, with a fork length of 42 cm. In addition, during the survey period, one steelhead carcass was found on the Scott River mainstem. Scale samples and the head were submitted to CDFG. Predation of carcasses was high, especially during the early part of the survey period, when fewer carcasses were available.

Tissue and scale samples were collected from a total of 136 carcasses (73 female, 63 male) throughout the basin. All sample sets were submitted to Mark Pisano (CDFG). These samples will be submitted to NOAA and CDFG labs for genetic analysis, and scale sample analysis. To date this analysis has not been completed. See Appendix D, Carcass Sample List, for location and date of carcass sampled.

Stream Temperature

Stream Temperature data was collected at hourly intervals from November – January 31st. Temperature data was collected in the lower South Fork, Lower Sugar Creek, Mid-French, and Lower Mill. The datalogger deployed in Sugar Creek malfunctioned, and some data from the key spawning period was lost.

There is significant variation in temperatures between the tributaries. Sugar Creek and French Creek are coldest, with temperatures ranging between .5° C - 4.3°C during the spawning period. This data is supported by observations of Sugar Creek and French Creek being iced over during surveys. During the survey of November 24th, 2004, lower Sugar Creek had sheets of ice on the edges, as thick as ½ to ¾ of an inch. During surveys on January 13th, 2005, Miners Creek had sheets of ice over 70-80% of the stream, and French Creek had ice over 30% of the stream, measuring ¾ of an inch thick.

Frozen side channel of French Creek – January 6th, 2005

Shackleford and Mill were surveyed during the same period (January 11th and 12th), and showed no evidence of icing over. Temperatures in Mill Creek during the same period ranged from 5.3 - 8 °C. Hand held thermometer recordings in Mill Creek showed temperatures of 6 - 7°C degrees during the survey period. See Figure IV for temperature data during the survey period.

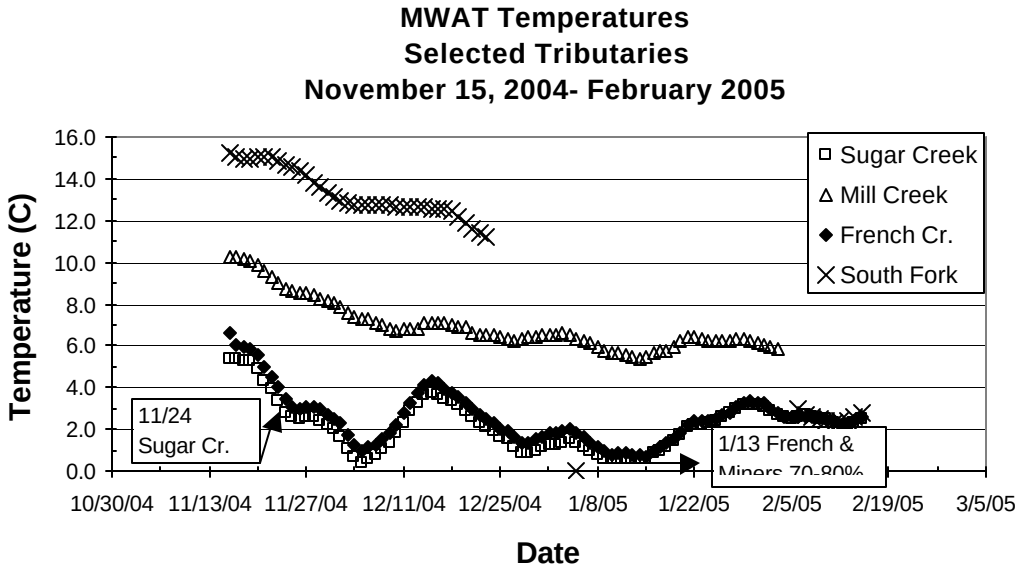


Figure IV**. Stream Temperatures in selected tributaries.**

Site Specific Factors

During the redd surveys, redd dimensions (length, width, pott depth), and substrate composition were measured when it would not cause disturbance to the spawning fish. See Table V for average conditions by reach.

Mark and Recapture – Population Estimates
Mark and recapture studies were completed in Shackleford-Mill and French-Miners Creek. Population estimates were generated for individual reaches using Peterson and Schaefer estimates. Mark and recapture was completed in Lower French Creek (.70 Mi), Middle French Creek (1.62 Mi.), Miners Creek (.9 Mi), Lower Shackleford-Mill (2.17 Mi) and Lower Mill Creek (1.6 Mi).

Lower French Creek was dropped from the population estimate due to: low number of marked carcasses (< 25) and a missed survey week.

Mark and Recapture of Coho Carcasses
A weekly survey of all mark and recapture reaches was completed to get tagged fish out, and to recover tagged fish. This was six weeks in French Creek, and four weeks in Shackleford-Mill. Large amounts of spawning and good survey conditions in these reaches allowed for relatively high rates of carcass capture and recapture.

The short duration of spawning (December 13th – Jan 11th in Shackleford) and clustered period of die-off of spawners (Dec 20th –Jan 6th for Shackleford) along with the use of a weekly survey (rather than semi-weekly) caused the number of mark and recapture trials to be reduced to a relatively small number. Additionally, the relatively small reach size created a small sample size per reach, increasing the error in estimates.

Population Estimates
The mark and recapture data collected was utilized for estimates using two equations: the Peterson Estimate and the Schaeffer Estimate.

The Peterson equation estimates the population using all the data as a single trial

$$N = MC/R$$
(Equation 3.5 Ricker 1975)

N = size of population
M = number of fish marked
C = catch or sample taken for census (total number of carcasses)
R = number of recaptured marks

The Schaefer equation stratifies the data over time. The use of individually numbered tags allows for the recording of when a fish is both marked and recaptured.
Schaefer Equation:

$$N = ? (R_{ij} * Mi/R_i * C_j/R_j)$$
Equation 3.19 (Ricker 1975)

For the Schaefer estimate, the periods of marking is designated by i , and periods of recapture designated by j.
M_i = number of fish marked in the ith period of marking
M= total number marked

C_j = number of fish caught and examined in the j^{th} period of recovery
R_{ij} = number of fish marked in the i^{th} marking period which are recaptured in the j^{th} recovery period
R_i = total recaptures of fish tagged in the i^{th} period
R_j = total recaptures during the j^{th} period.

The above data is arranged into a table, as shown in Appendix C.

The Schaefer equation produces estimates for each survey period (week). In this way the Schaefer estimate compensates for different mark and recapture rates experienced during the season.

Table VI contains the results of the Peterson and Schaefer estimates.

Table VI. Population Estimates from Mark and Recapture Data.

Reach	Peterson (Confidence Interval)	Schaefer (Confidence Interval)	Marks	Recaps	Live count	Redd count	Carcass count
Mid-French	181 (156-209)	163 (140-190)	70	50	142	49	82
Miners Creek	221 (193-252)	133 (112-157)	71	47	281	43	100
Lower Mill	337 (299-374)	307 (274-343)	142	115	273	127	154
Lower Shackleford	201 (174-230)	110 (91-133)	63	40	170	76	86

The Population Estimates and field data collected for these reaches agree within reason. In Shackleford- Mill the estimated fish population, based on redd counts is 254 adult fish (redd count x 2) for Lower Mill, and 152 adult fish for Lower Shackleford. This is extremely close to the live counts for those reaches. In Lower Mill these numbers are also close to the Scheafer estimate. In Lower Shackleford the number agrees with the average between the Peterson and Schaefer. In French Creek, the live count agrees with the estimates, but exceeds the expected population based on redd count. This in part may be due to superimpostion of redds, as well as incidences of multiple fish on redds. The estimates are furthest off in Miners Creek. This may be due to various factors, including: superimpostion of redds, short period of marking (especially Shackleford-Mill), multiple fish on redds, and during the last survey completed 25 of the 71 marked carcasses were still not recovered, 19 from the previous survey week. However the stream was 70-80% iced over, with no visibility through ice. Due to this, only 6 carcasses were retrieved.

Extent of Spawning Distribution and Habitat Characterization by Stream

Flow conditions during the survey period (November 16^{th} – January 14^{th}) allowed for distribution of coho spawning throughout most of the basin. Coho were observed in all tributaries surveyed with the exception of: Middle Creek, Boulder Creek(Scott), Boulder Creek (S. Fork), Paynes Creek, Grouse Creek and Rail Creek (with the exception of

spawning observed in an unsurveyed reach.). In addition, lack of connectivity prevented access to Moffet-McAdams, Rattlesnake Cr., Indian Creek, and Patterson Cr. (Fort Jones) The following are descriptions of spawning distribution, and habitat characterization by tributary, for selected survey reaches.

French Creek

French-Miners Creek was surveyed in six reaches totaling 5.93 miles. Three reaches were surveyed weekly for mark and recapture: Lower French Creek, Mid- French Creek, and Miners Creek. Additional reaches surveyed once were French Creek near Paynes Creek, French Creek near Duck Lake Creek, French Creek below the North Fork, the North Fork French Creek, and lower Paynes Creek. See Map #4 for reach locations and redd distribution. The upper extent of spawning documented was approximately ¼ mile upstream from the confluence of Paynes Creek. However, the heaviest spawning activity was French Creek below the confluence of French and Miners Creek, and in lower Miners Creek. Surveys have never been completed in Miners Creek above the .9 mile point; spawning likely occurs above this point.

Habitat Characterization - Mid French

The section from Miner's Cr. confluence to the lower Miner's Cr. Road bridge (Index Reach in 2001) offers a combination of frequent occurrence of spawning gravels with exceptional cover. Large amounts of the available spawning gravels appeared to have a high occurrence of fine sediment interspersed, with the occurrence of sand (DG) in many redds. This reach has a relatively mature riparian corridor mostly comprised of alders with an under story of willows, small trees, shrubs and blackberries. The channel is relatively well populated with small and larger wood, creating several log jams. A large amount of stable undercut banks exist and overhanging terrestrial vegetation is prevalent. The majority of the spawning coho were observed utilizing areas of suitable gravel adjacent to the channel margins, perhaps to gain the benefit of terrestrial cover and areas sheltered by wood. The one observed side channel had limited spawning, probably because this was one of the few areas that did not offer any overhead cover.

From the Miner's Cr. Road bridge down there is a younger riparian corridor that consists mostly of willows and small alder. This area has good to excellent occurrence of spawning gravel and several areas of utilized side channel / ditch inlet. Most side channel/ ditch inlet locations were utilized by at least a pair of salmon. Spawning was usually along a margin, near optimal overhead cover.

Shackleford-Mill Creek

Shackleford

Two reaches were surveyed in Shackleford Creek. See Map #5 for reach locations. The lower reach was established as a mark and recapture reach. Spawning was documented in the upper reach, below the falls.

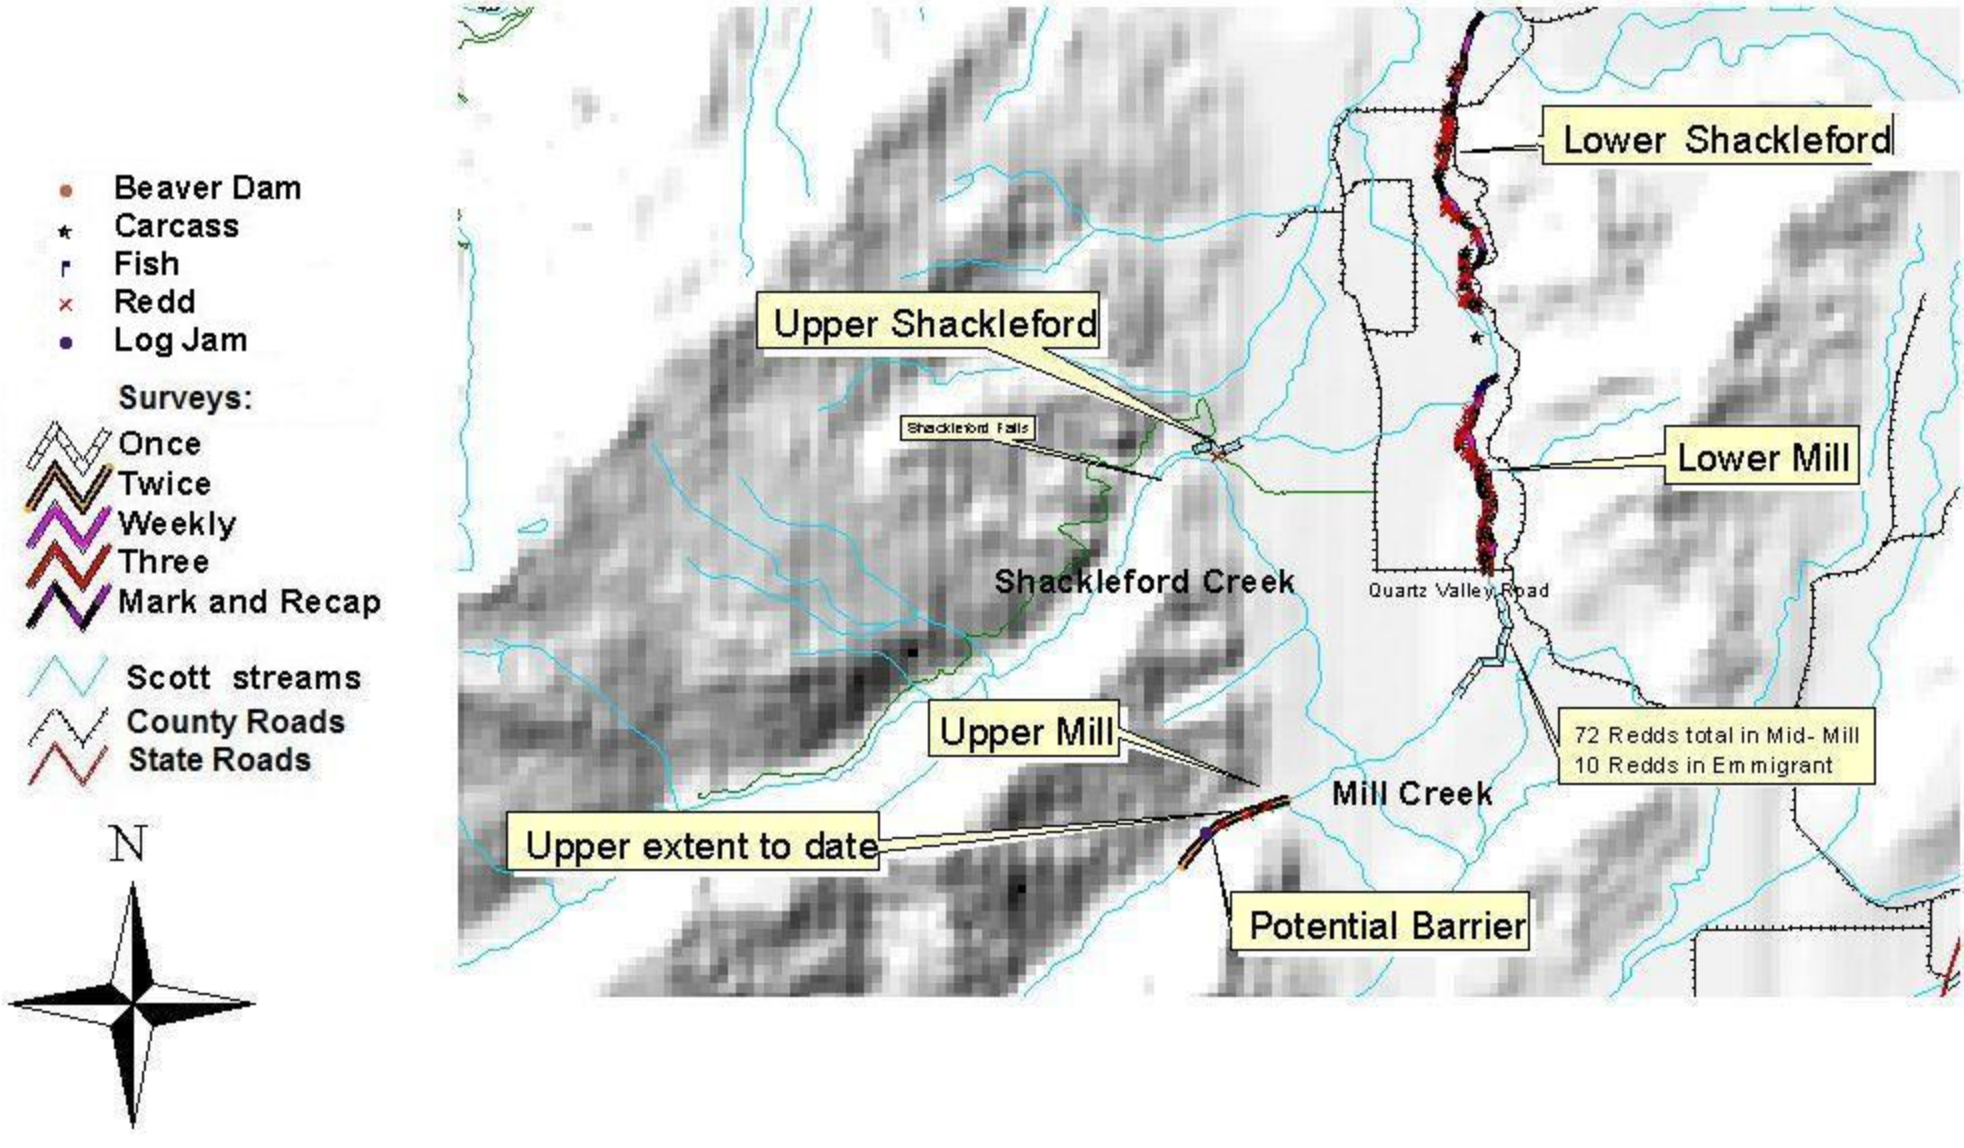
Map # 5
Redds - Shackleford-Mill



Mill Creek
Three reaches were surveyed in Mill Creek. The lower reach (2 mi) was established as a mark and recapture reach. See Map #5 for reach locations

Habitat Characterization –Lower Mill Creek
This reach exhibited large amounts of suitable sorted spawning gravel. Most of the available gravel appeared to be low in interspersed fine sediment. Coho were observed spawning throughout the reach, mostly utilizing channel margins and side channels that offered direct cover from riparian vegetation (mostly willow, alder, sedge, blackberry), due to the small channel size and ideal substrate (gravels). Coho were also found in more mid-channel locations without direct cover from the surrounding riparian. The riparian corridor is mostly intact but less mature and not as wide as some reaches surveyed. Moderate amounts of small wood and larger wood were interspersed throughout reach.

The existence of a huge beaver dam at the lower end of the reach created an area that has multiple side-channels surrounded by cover (mostly willow) creating a point on the stream that has greatly increased habitat for spawning and rearing.

Habitat Characterization - Lower Shackleford
The stream channel is considerably larger (flow volume and wetted width) than Lower Mill Cr. because of the influence of Shackleford Creek. This reach maintains a good riparian corridor and decent wood occurrence, until the last 1/3 mile. The last 1/3 mile of Shackleford has no riparian or channel structure. Overall the reach has excellent gravel quality and occurrence with little fine sediment. Spawning was throughout this reach, with side-channels highly favored. Also main stem margins were utilized in association with overhead cover**.** Relatively large amounts of side-channels that were connected during the time of spawning started to become de-watered due to low flows caused by extreme cold weather.

East Fork Scott

The East Fork Scott River was surveyed in three reaches: Lower Masterson Road, Upper Masterson Road, and the Upper East Fork (including sections of Houston and Crater Cr.), for a total of 6.5 miles. In addition, reaches in Rail Creek, Grouse Creek and Kangaroo Creek were surveyed, for a total of 2.6 miles. See Map #6 for reach locations, and redd distribution. The biggest gap in this survey effort was the lower five miles from Grouse Creek to the confluence with the South Fork. Spawning likely occurs in this reach, however, access was not granted to survey.

The Upper East Fork reach encompassed the confluence with Crater Creek and Houston Creek, and ½ mile downstream. (RM 13) No fish were observed in this reach, and it is probably more suitable for steelhead spawning. The farthest upstream spawning was documented at River Mile 8.0, although live fish were sighted at River mile 10.2. Observed spawning was approximately 2 miles higher than previously documented. The most spawning activity was observed in the section one mile upstream of the confluence with Grouse Creek. In addition, spawning activity was documented in the lowest 1 mile of Kangaroo Creek.

South Fork Scott

The South Fork Scott River was surveyed in two reaches totaling 2.3 miles. See Map #7 for reach locations, and redd distribution. The Lower South Fork reach is approximately .4 miles on USFS land just behind the town of Callahan. The Upper South Fork reach begins 800 meters upstream from Fox Creek and goes to Boulder Creek. The biggest gap in the survey is approximately 2 miles between Boulder Creek and the lower South Fork, due to lack of access. Spawning likely occurred in this reach, as coho carcasses were observed from the road. Spot surveys were completed at the mouths of Fox and Boulder Creek, but no fish or spawning activity was observed.

During this survey period no spawning was observed in the Lower South Fork reach. The uppermost extent of spawning was in the Upper South Fork Reach, 300 meters below Fox Creek. This is lower than that documented in 2001. Overall the number of redds observed in 2004 was significantly lower than in 2001 (10 vs 68). The spawning habitat available in the South Fork of the Scott is not comparable to that found in many other tributaries (such as Shackle-ford Mill or French Creek). This is due to the higher gradient, and larger substrate size. Flow conditions during the spawning period of 2004 likely contributed to a greater dispersion of coho salmon than 2001, which was a drought year. Flows during December 2004 allowed coho access to areas of suitable habitat throughout the watershed.

Habitat Characterization – Upper South Fork

This reach appears to be largely limited for spawning by the area of sufficient sorted gravels and side channel occurrence. The small amount of side channels in the surveyed area – both natural and ditch inlets – were usually occupied with at least a single redd. Additionally, one ditch inlet possibly had multiple redds. A few redds were observed in margins of the main channel when suitable gravel was associated with overhead cover. A large part of the reach did not have much suitable gravel. This is likely caused by a higher gradient channel and a stream structure impacted by historic mining and upslope management. Overhead cover in South Fork included terrestrial vegetation and an assortment of small and larger woody debris.

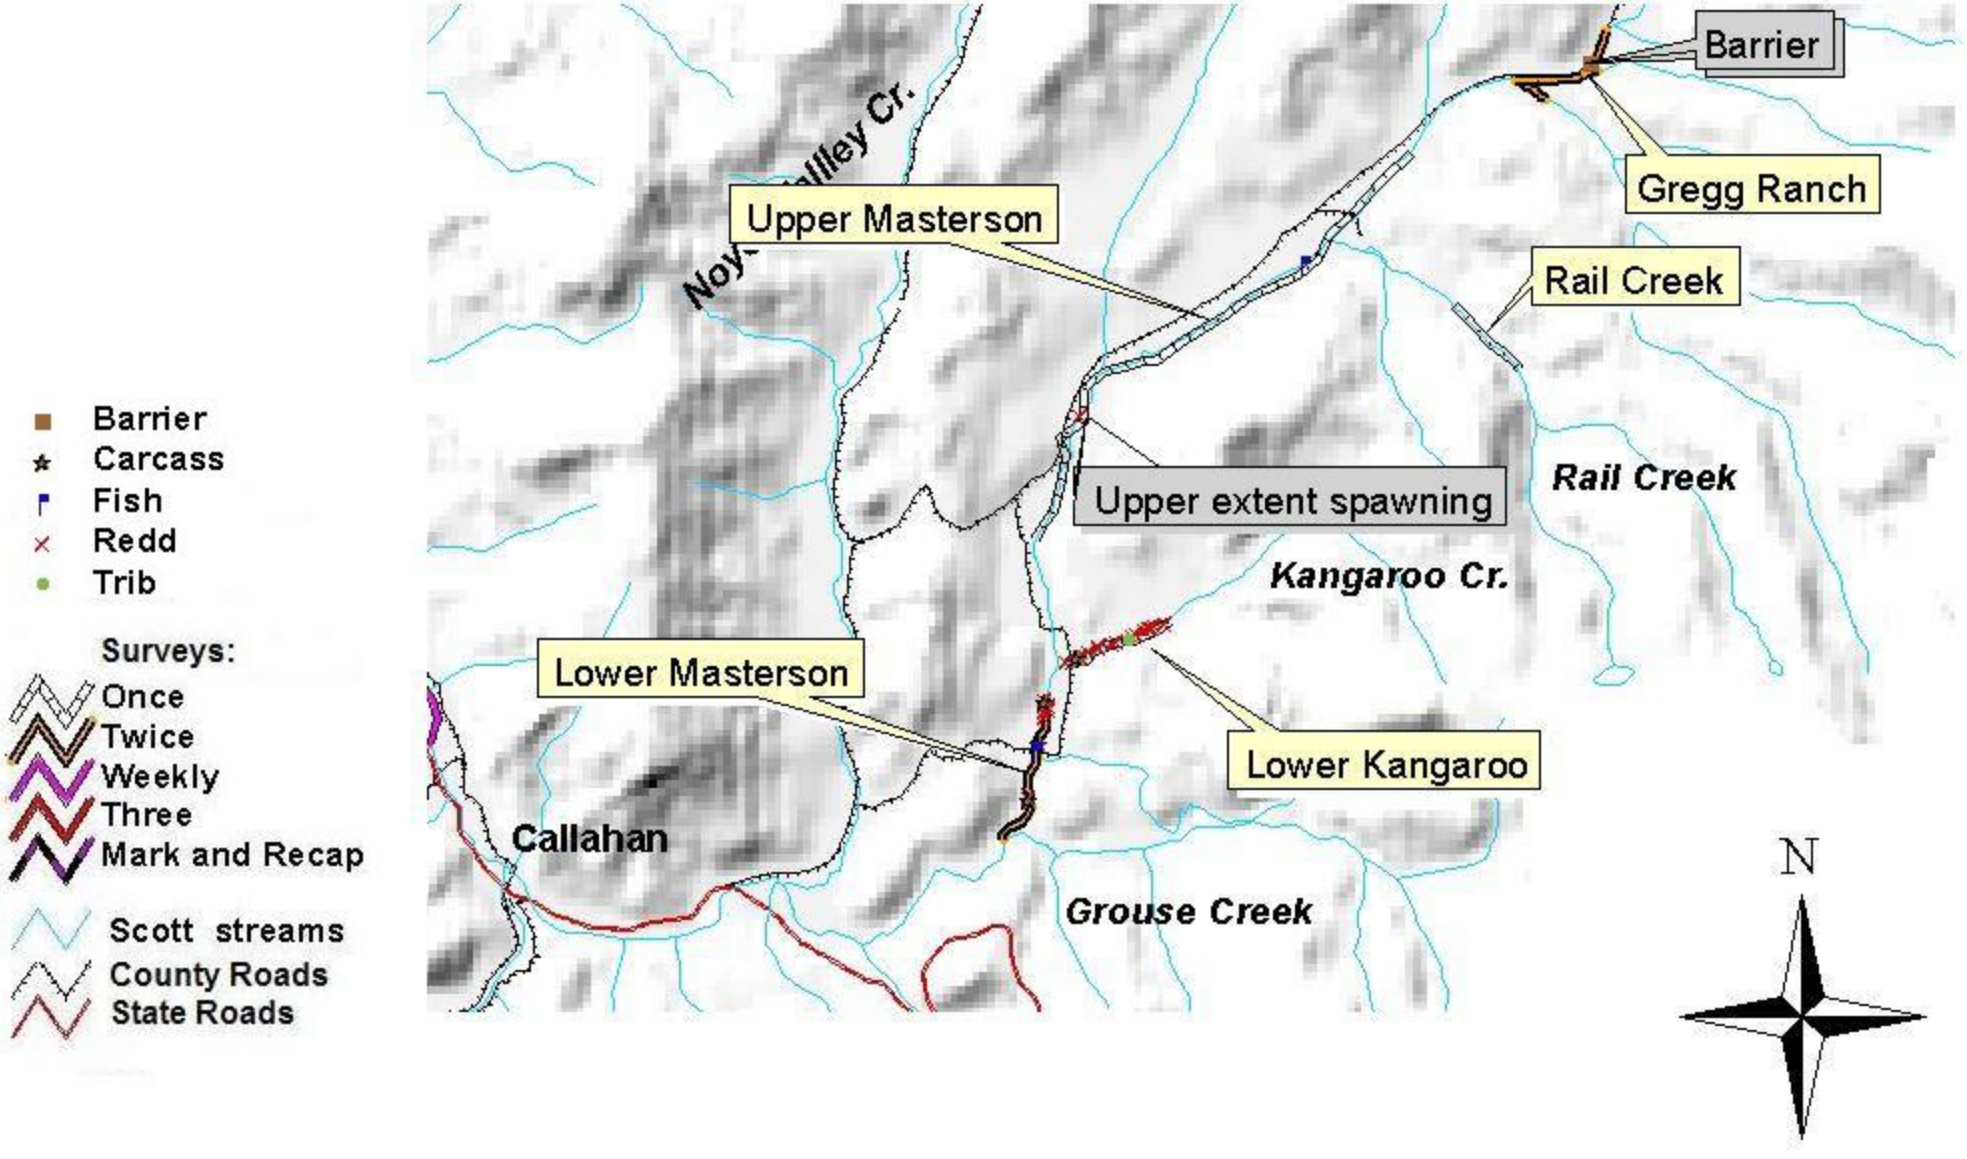
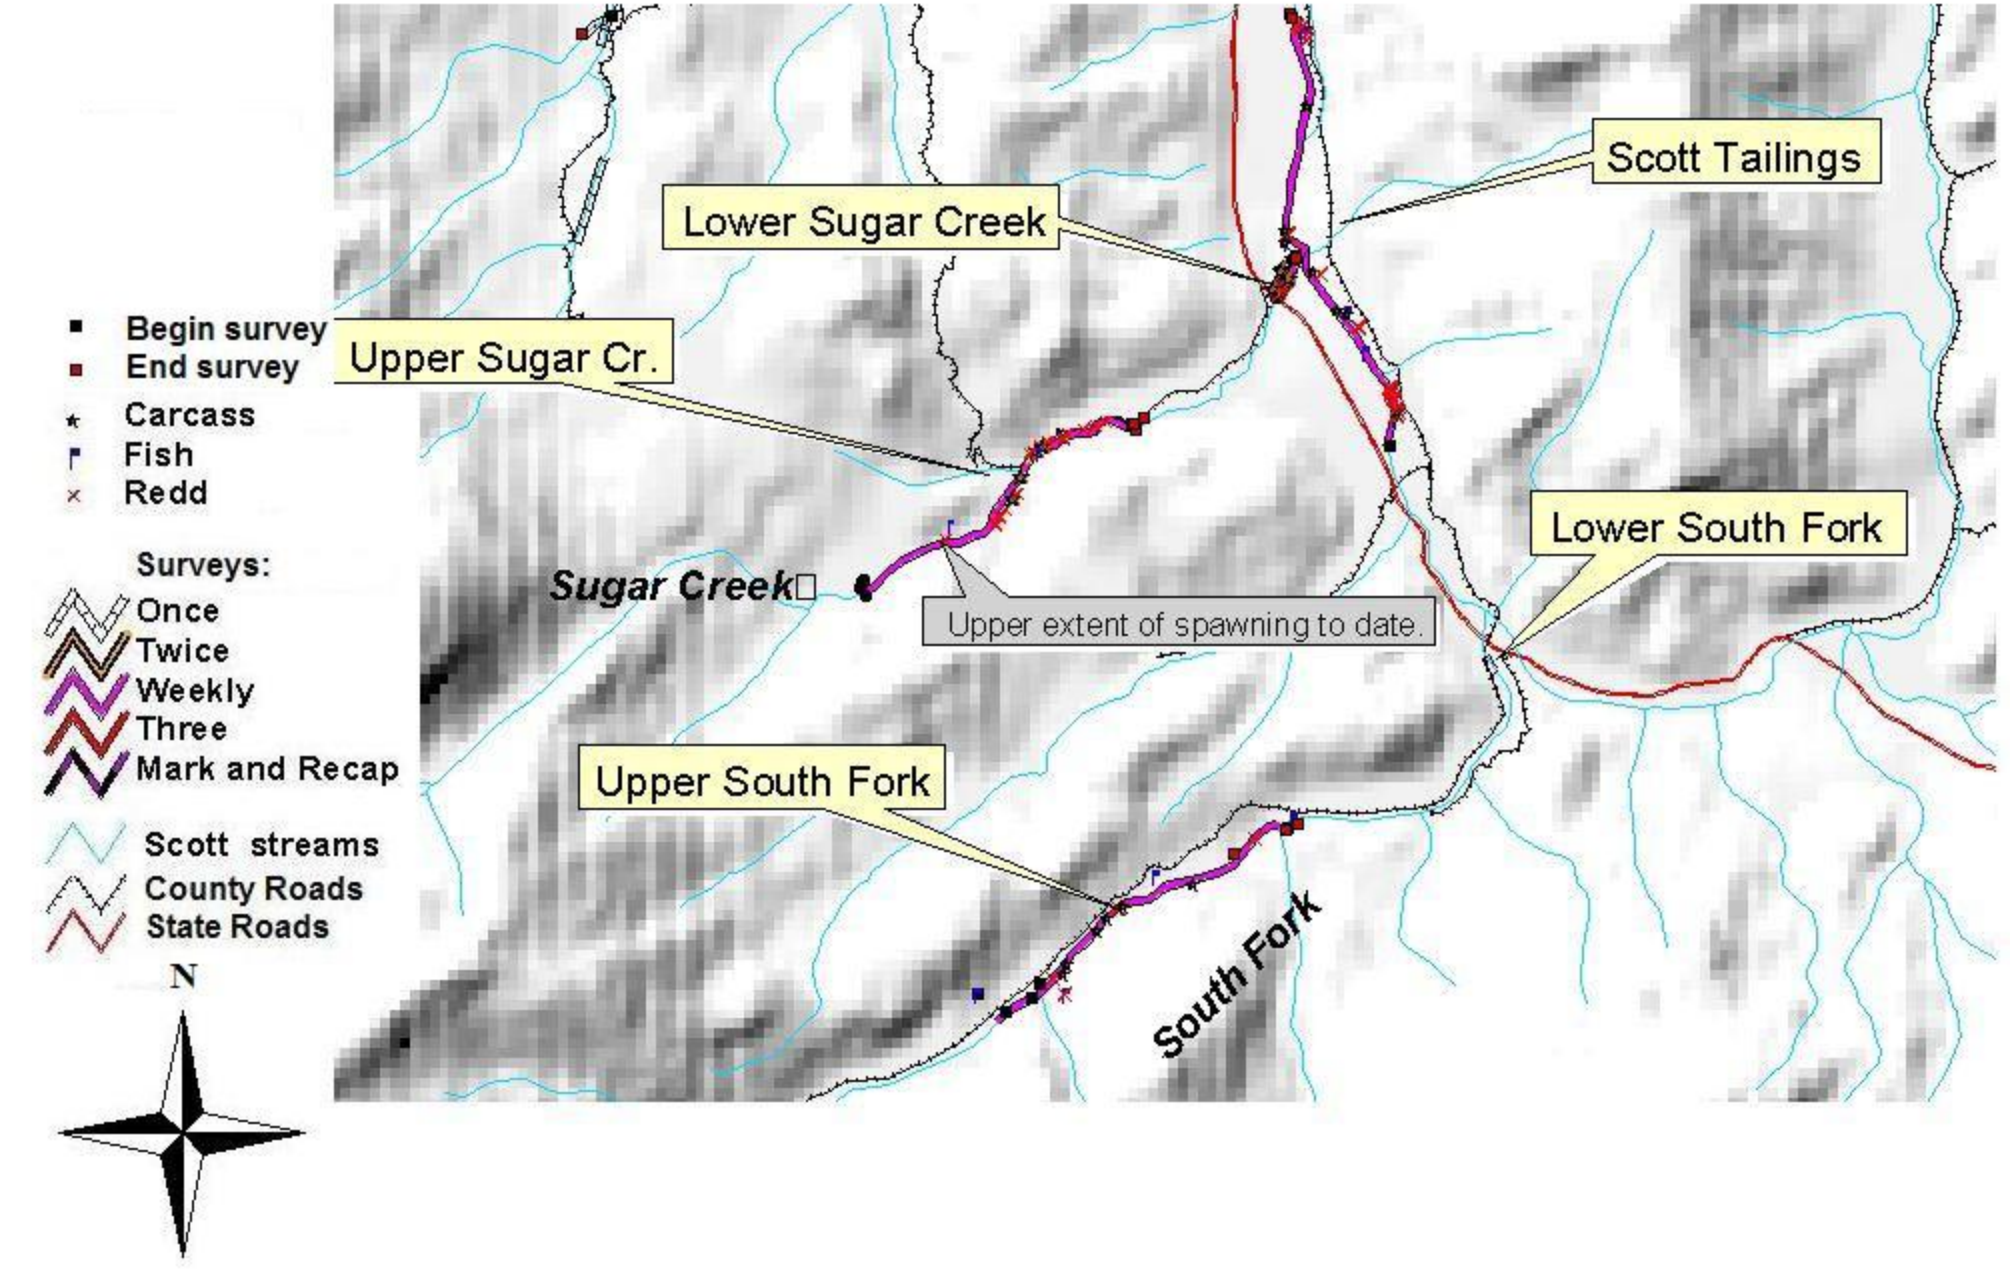
Map # 6
East Fork Scott River



Scott River 2004/2005 Adult Coho Surveys
Map # 7
Sugar Creek, Tailings, South Fork



Coho male in side channel of South Fork Scott River – December 23, 2004

Sugar Creek

Sugar Creek was surveyed in two reaches totaling 2.8 miles: Lower Sugar Creek is Hwy 3 to the mouth, and Upper Sugar Creek is from mile 2 to mile 4. See Map # 7 for reach locations, and redd distribution. Low flows and a beaver dam at the mouth created a barrier to passage until the early December rains. The Lower Sugar Creek was heavily used for spawning, with multiple fish on redds, and redd superimposition occurring. The uppermost extent of spawning documented was 3.48 miles from the mouth of Sugar Creek, above the confluence of Tiger Fork. Upper Sugar Creek received more spawning activity than observed in 2001.

Habitat Characterization – Lower Sugar Creek

This section of Sugar Creek contains areas with abundant spawning gravels and received a high concentration of coho spawners. Fish were observed creating large redds, superimposing redds, and utilizing non-standard pairing (up to six fish on "1 redd"). It appeared that the redds on Sugar Cr. were less directly associated with a component of overhead cover. Many of the redds did have riparian cover (alders, willows, sedges) in their vicinity. But, there were also redds that were near the middle of the channel with the closest cover being offered by the riparian vegetation. The spawners would quickly utilize this bank cover if startled – darting to undercut banks with terrestrial vegetation which are common in this section.

Habitat Characterization – Upper Sugar Creek

This reach is higher gradient with larger size substrate (large cobble and boulder). Upper Sugar Creek has many significant pools, and few areas of suitable spawning substrate. During this spawning season, most suitable substrate was utilized by coho. Cover is abundant throughout the reach, consisting of undercut banks, woody debris, and riparian vegetation. Sand, primarily decomposed granite (DG) is present throughout most of the reach.

Scott River Mainstem – Tailings Reach

The tailings reach was a total of 2.75 miles, beginning approximately 0.4 miles downstream from the confluence of Wildcat Creek to 1.5 miles downstream from Sugar Creek. See Map #7 for reach location, and redd distribution. Following the rains of December 6th – 8th flows were too high to safely survey this reach. Spawning was documented in the reach during late November through early December. This may be due in part to a beaver dam at the mouth of Sugar Creek, which prevented access to Sugar Creek until after December 10th. Most of the spawning occurred in the upper section of the reach (above Sugar Creek) which had not been surveyed previous to 2004.

Habitat Characterization – Tailings Reach

Main portions of the stream had large amounts of sorted gravels in the pool tail outs that appeared to be suitable size for coho salmon but these tail out locations contained absolutely no cover and the coho salmon did not utilize these sorted gravels. These areas of sorted gravel are would be suitable habitat for Chinook salmon if access were possible during the Chinook spawning season. The coho salmon that were observed on redds were mostly utilizing side-channels that had smaller volumes of flow – this was seen in natural side-channels and locations such as Farmer's ditch inlet. The coho spawning in the side-channels were mostly spawning directly under cover – almost always offered by terrestrial vegetation (alders, blackberries, sedges, willows). Smaller amounts of the spawning coho were utilizing the extreme margin of the mainstem river in areas that they found suitable spawning gravels under direct cover. It appeared that the main driving force to spawning location was the presence of gravels directly associated with overhead cover. Large sections of this survey reach were devoid of spawning, despite suitable gravels, possibly due to lack of available cover.

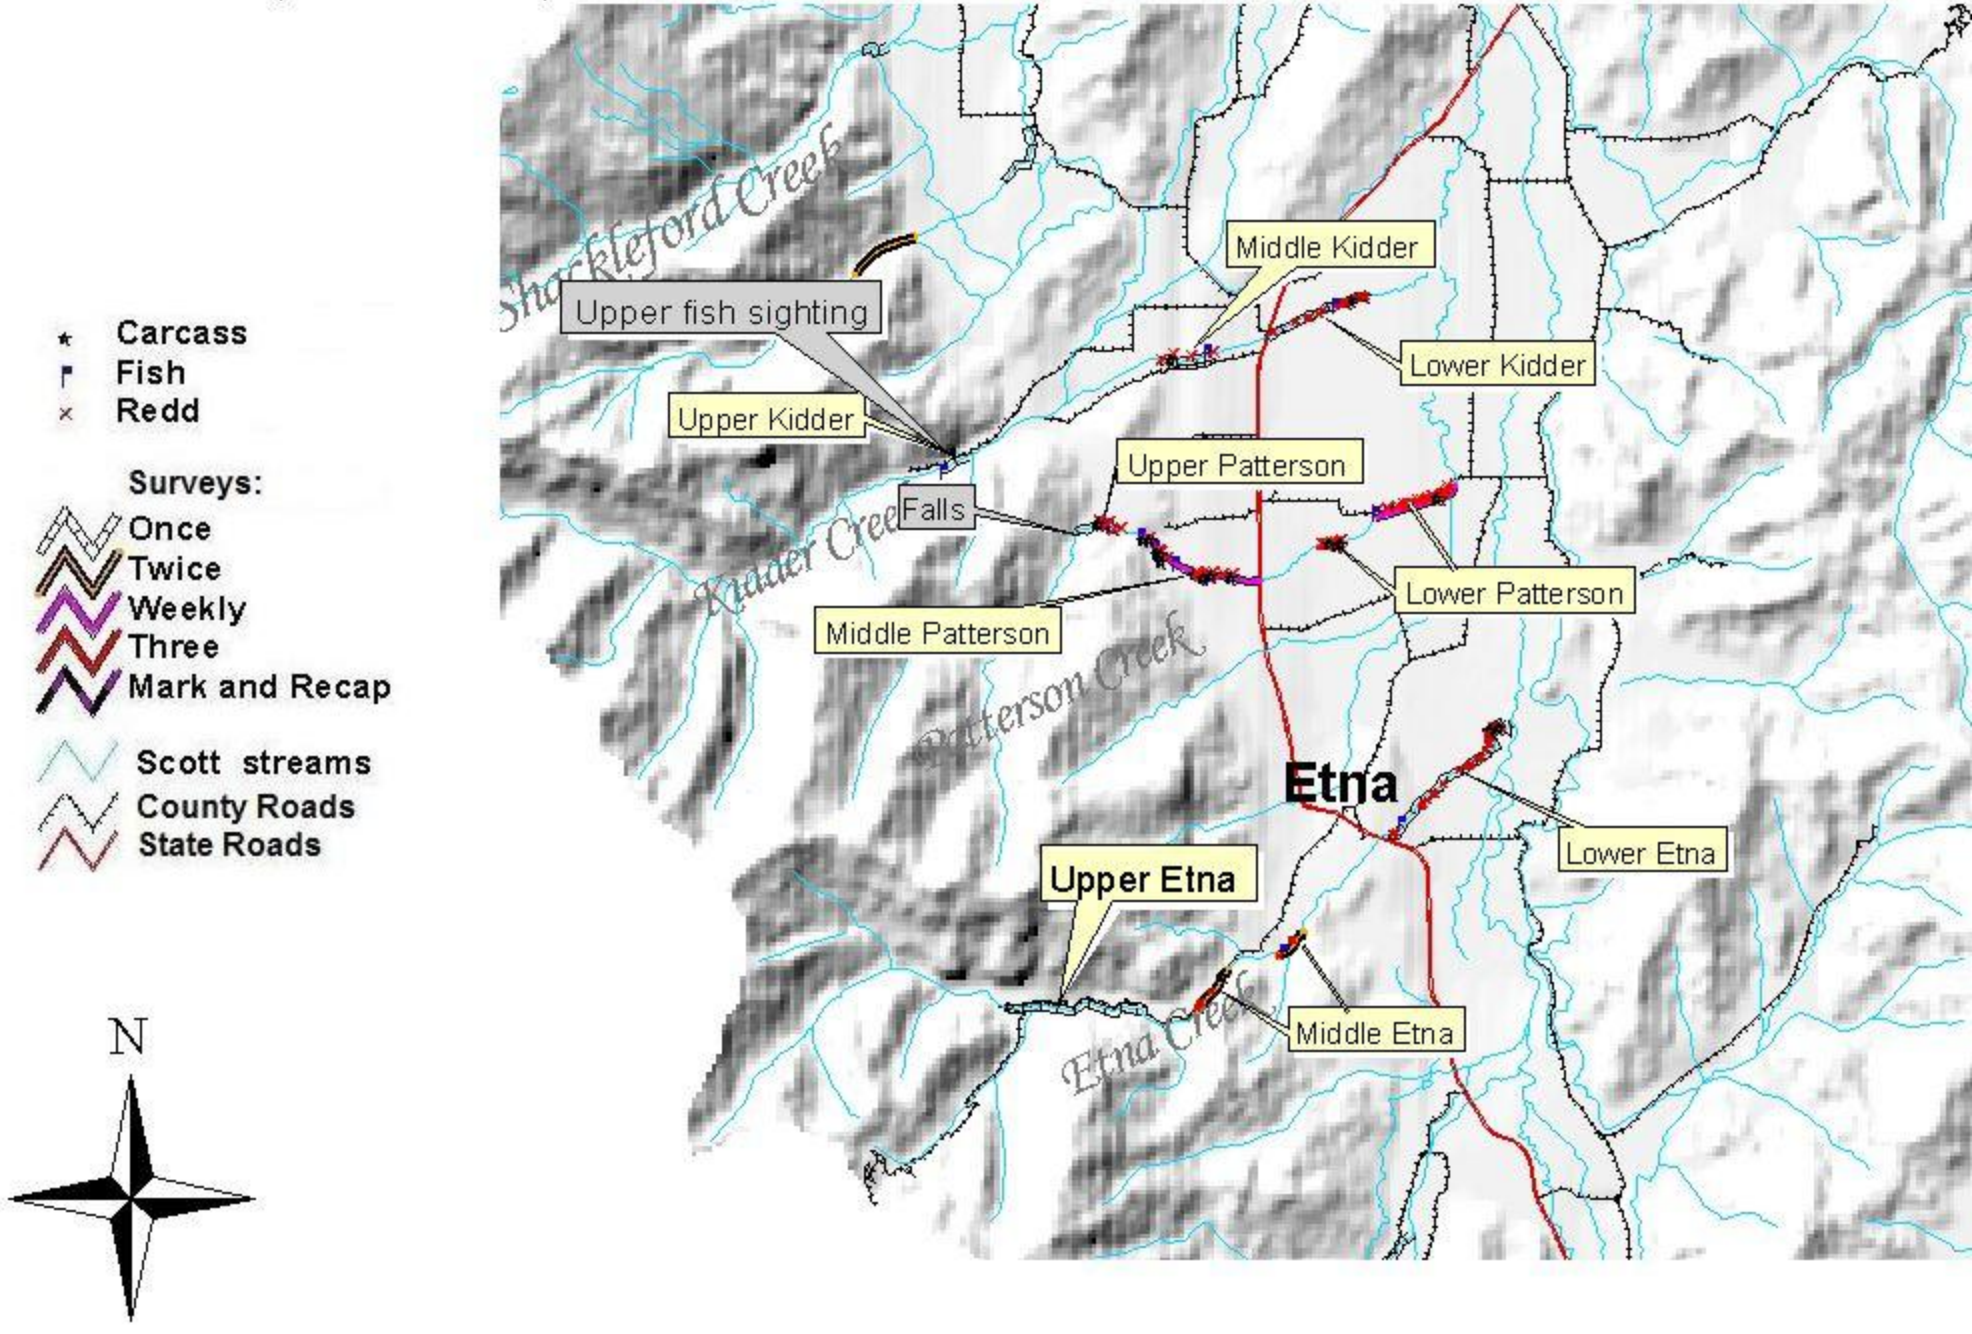
Etna Creek

Three reaches were surveyed on Etna Creek totaling 4.9 miles, and an additional .2 miles of Ruffy Gap Creek, which was dry at the time of survey. The upper extent of the survey was at the confluence of Mill Creek, at river mile 8.0. See Map #8 for reach locations and redd distribution. The fish ladder at the Etna City Diversion was not in place during the first survey on December 17th, but was in place at some point after that. The upper extent of spawning was documented at the Etna City Diversion (RM 5.5). The heaviest spawning activity was in the lower 2.25 miles below the Hwy 3 bridge.

Habitat Characterization –Lower Etna

Near the confluence with the Scott River, abundant sorted spawning gravels and over hanging cover was present, although spawning density was not high. The locations where spawning density was highest was where channel shaping had occurred during the summer of 2004. In these areas the gravels were looser, and the size of sorted gravels was suitable for coho spawning. As the gradient increased closer to HWY 3, available spawning gravels were limited to active side channels. The main channel was dominated by oversized material for spawning. Both side channels and the main channel were lacking overhanging vegetation throughout the reach. The surveyed reach loses connectivity in June and remains dry until December.

Scott River 2004/2005 Adult Coho Surveys
Map # 8
Kidder, Patterson, Etna Creek



Habitat Characterization –Middle Etna

The two reaches surveyed between the Etna City Diversion and Etna City were believed to be limited in spawning by the lack of suitable gravels. The area surveyed was a relatively large high gradient channel that contained substantial amounts of cobble. There is a good to excellent amount of cover from wood and riparian vegetation throughout the reach. The few redds observed were located in 1) the margin of the main channel under cover or 2) in the one side channel surveyed, which had limited cover.

Patterson Creek

Three reaches were surveyed on Patterson Creek, totaling 2.9 miles. See Map #8 for reach locations. The lower reach (Lower Patterson) was a split reach, due to lack of access. The upper extent of spawning documented was approximately ¼ mile downstream from the falls at river mile 7.7. The heaviest spawning occurred in the lower reach, just upstream from the confluence of Johnson and Patterson Creeks.

Habitat Characterization – Lower Patterson

Quality sorted gravels and gradient were found throughout the two surveyed reach segments. Adequate to abundant overhanging vegetation was also present throughout the lower surveyed reaches. Coho primarily selected spawning along the margins of the stream, but the center of the stream was utilized as well. There were areas where sorted gravels were present and overhanging vegetation was plentiful throughout. The biggest concern related to spawning conditions in Patterson Creek was the lack of flow between rain events (exacerbated by cold dry conditions). If coho did not access Patterson during a one week period after the rains event in early December, access was limited. By December 20th, flows were less then 2 cfs in the lower reaches, even after all stockwater diversions were voluntarily shut off to aid the coho. The low flows may have had an impact on some of the redds, which appeared to dry out, and then freeze in the cold weather.

Coho pair in Lower Patterson Cr.

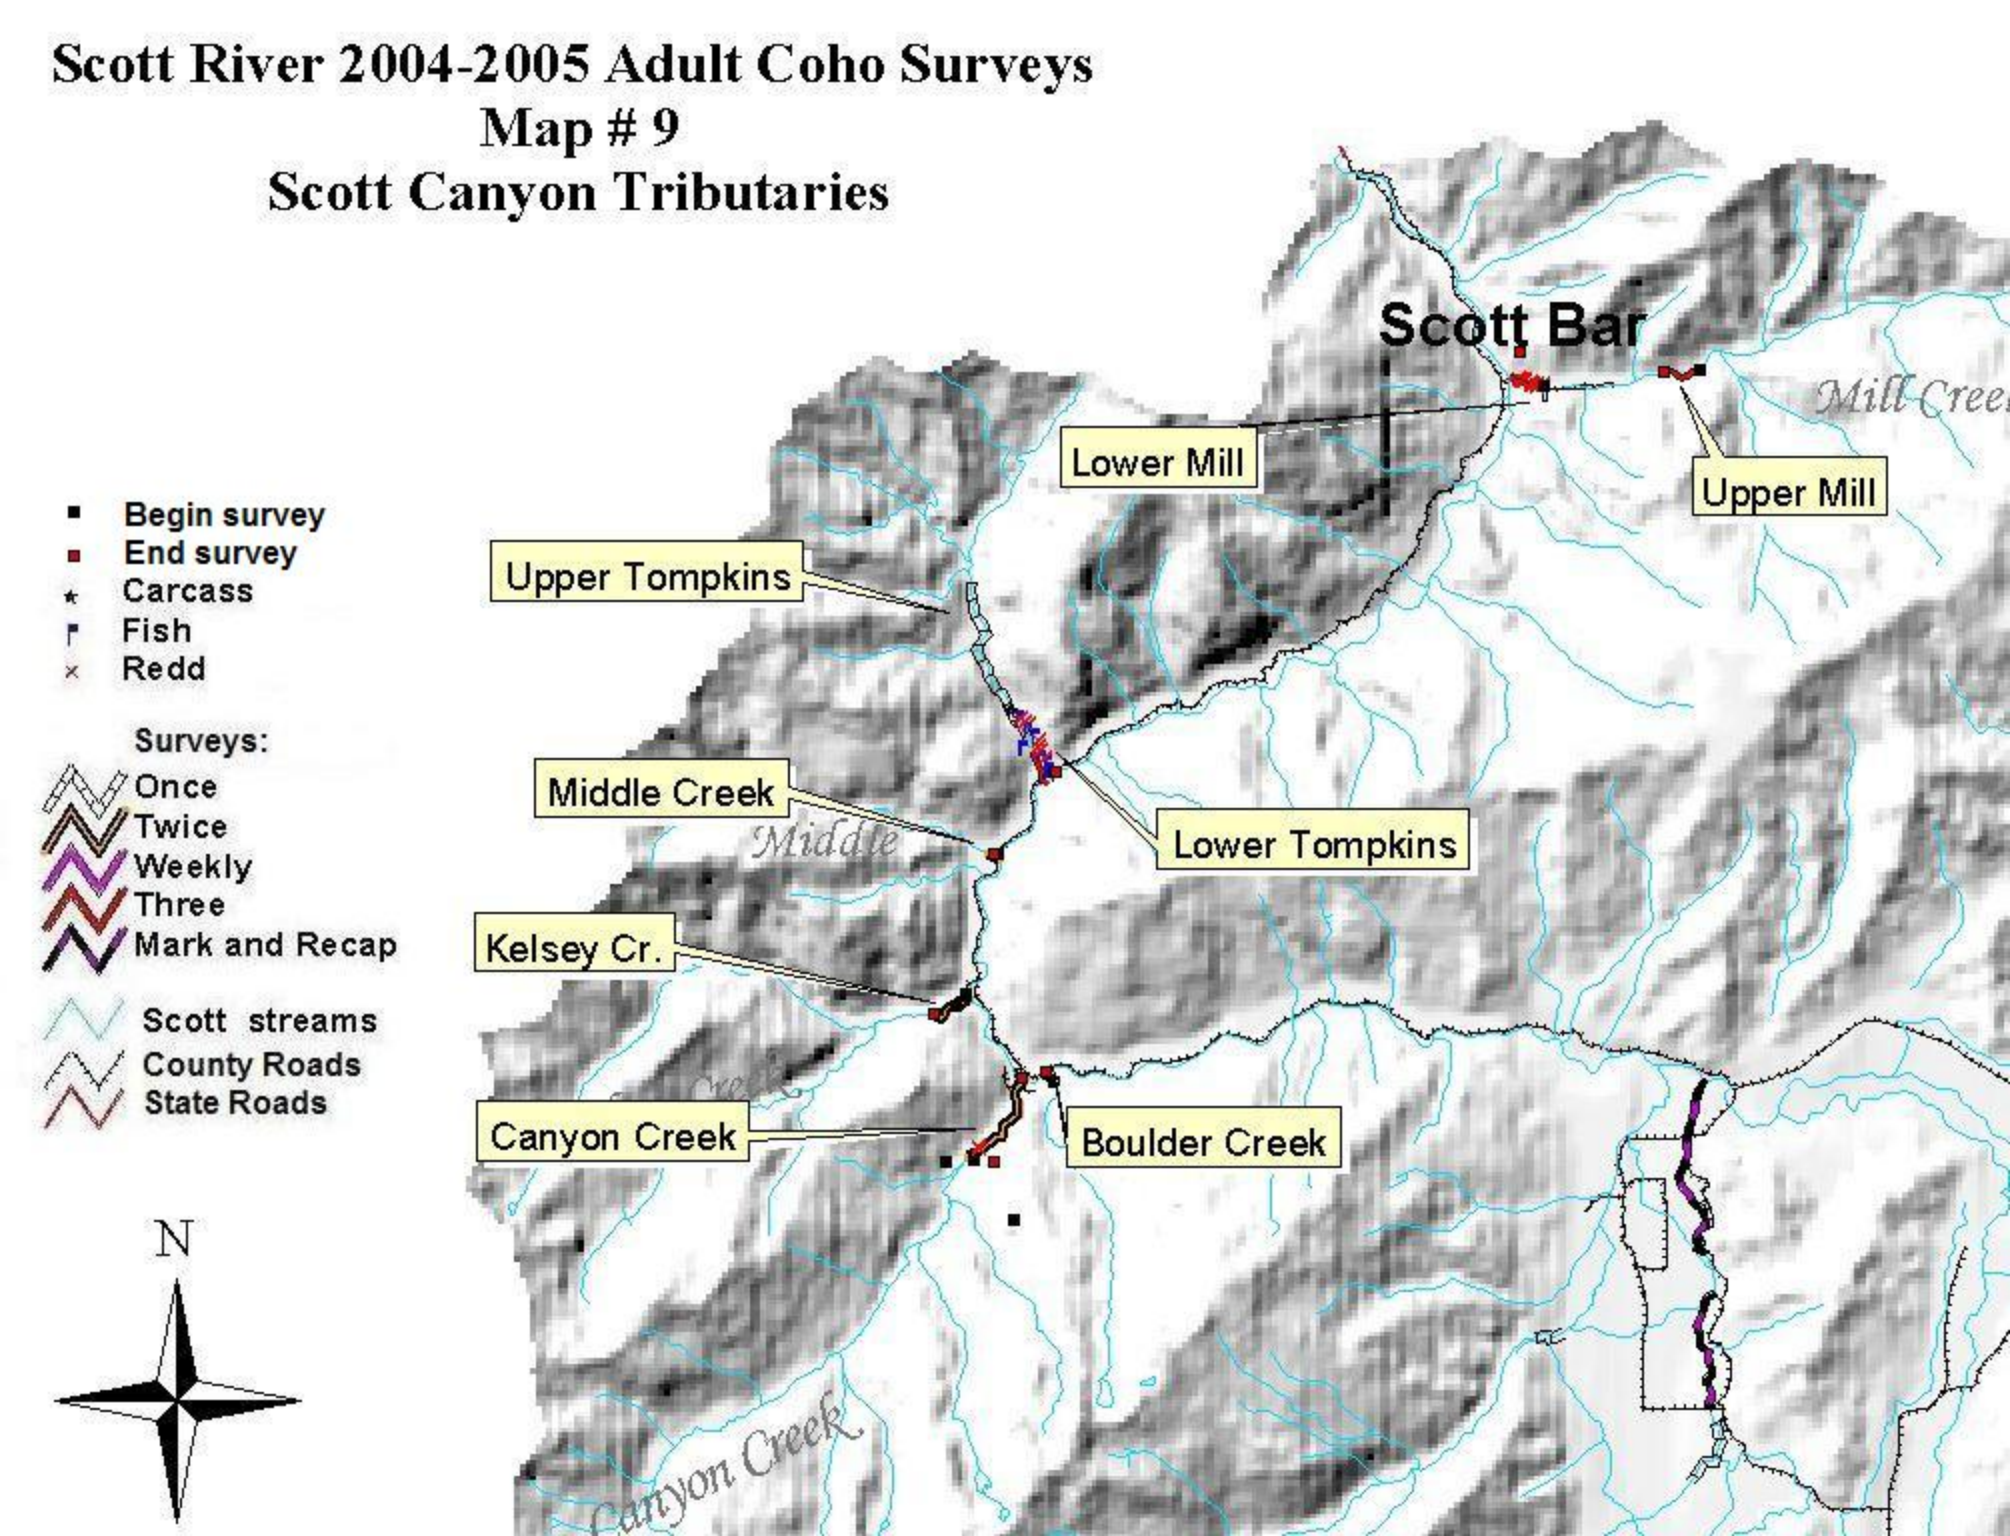
Habitat Characterization –Middle Patterson
This reach is relatively low gradient, with abundant suitable gravels. Gravels in this reach appear clean, with little sediment. Cover is abundant, in the form of woody debris, log jams, and riparian vegetation.

Kidder Creek

Three reaches were surveyed on Kidder Creek, totaling 2.40 miles. The highest survey reach was at 8.0 miles from the mouth. See Map #8 for reach locations. The upper extent of spawning documented was approximately one mile upstream from Hwy 3. However, a coho pair was seen 4 miles upstream from Hwy 3. The heaviest spawning activity was in the 1.1 mile reach below Hwy 3.

Habitat Characterization –Lower and Middle Kidder Creek
The Lower Kidder Creek reach is low gradient, and contained the best spawning gravels found in Kidder Creek. Quality gravels were found in the lower gradient reaches where the active channel was confined and slightly entrenched. Overhanging vegetation was present in both Lower and Middle Kidder, as were adequate sorted gravels. Coho preferred the margins where spawning gravels were present. Some channel shaping had occurred in Lower Kidder during the fall of 2004, which loosened the gravels in the lower reaches surveyed. This area was preferred by coho, and many of the redds were superimposed. Spawning sites were selected in locations where flows were slower then usual. The redds (potts) through this reach seemed deeper, perhaps because the gravels

Scott River 2004-2005 Adult Coho Surveys
Map # 9
Scott Canyon Tributaries



were loose. Spawning activity notably decreased in locations where channel disturbance did not occur, potentially due to a lack of suitable gravels.

Most of the spawning was on margins and side channels (in both Lower and Middle Kidder). The active channel was wide, with little available cover. Available spawning gravels decreased as gradient increased. Oversized cobble dominated the channel from .4 miles below HWY 3 through the Middle Kidder Creek reach located .5 miles above Hwy 3. Again cover and available spawning gravels were scarce. The surveyed reach loses connectivity in June and remains dry until December.

Scott Canyon Tributaries

Scott Bar Mill, Tompkins Creek, Middle Creek, Kelsey Creek, Canyon Creek and Boulder Creek were surveyed in the Scott River Canyon. Two reaches were surveyed in each of Tompkins Creek and Scott Bar Mill. Spawning was documented in Scott Bar Mill, Tompkins Creek, Kelsey Creek and Kelsey Spawning Channel and Canyon Creek. See Map #9 for reach locations and redd distribution.

Mill Creek (Scott Bar)

Two reaches of Mill Creek near the town of Scott Bar were surveyed three times during the 2004-2005 season. The first survey occurred on November 22nd, and the last on December 28th, 2004. Lower Scott Bar Mill starts approximately 0.2 miles from the confluence and ended at approximately RM .5. Upper Scott Bar Mill began at approximately RM 2.5 and ended at RM 1.8. Lower Scott Bar Mill was heavily utilized in areas where suitable spawning gravel was present. No coho salmon or redds were observed in Upper Scott Bar Mill this season. However, several coho carcasses were observed in the section of Mill Creek between the Upper and Lower reach, where the road was close to the stream.

Habitat Characterization –Lower Scott Bar Mill Creek

This reach is low gradient, with pockets of abundant spawning gravels separated by larger cobble. The riparian corridor consists of large and small woody vegetation thick enough to prevent access to the stream in some places. Numerous redds and coho carcasses were found throughout this reach with redd superimposition occurring in some cases. Coho salmon redds and carcasses were observed below this reach down to the low water crossing near the confluence with the Scott River. Due to lack of access, the stream below this reach was not surveyed on foot, but portions were observable from the road.

Habitat Characterization –Upper Scott Bar Mill Creek

No coho were observed in this section of the creek in spite of apparently suitable spawning gravel. However two "test" redds were observed. This has a slightly steeper gradient than Lower Scott Bar Mill, riparian cover is present throughout the reach. Small woody debris and several pools are scattered throughout, providing potential rearing and holding habitat.

Discussion

Run Timing and Duration

Based on observations during the fall Chinook surveys, and Karuk Tribe radiotagging studies, adult coho entered the Scott River as early as October 22nd. Small amounts of mainstem spawning activity occurred prior to the heavy rainfalls of December 6th – 8th, indicating that coho hold in the mainstem until conditions were suitable for moving into the tributaries (ie. flow conditions). Radiotags and observations from the Fall Chinook Surveys (CDFG) documented adult coho holding in the Scott Canyon during most of November. The peak of the spawning period occurred after the tributaries regained connectivity, during the last two weeks of December, with little spawning activity following that period. It is highly likely that if rain and flow conditions allow, in any given year, spawning would occur earlier than that observed in 2004-2005.

Stream Temperature

Water temperature during incubation directly affects the rate of embryonic development, the timing of egg hatch, and the survival of embryos. Hatching and emergence time vary inversely with incubation temperatures (Konecki et al 1995). The affect of incubation temperatures on emergence timing can impact survival at the fry stage. Increased incubation temperatures can lead to early emergence and a longer growing season, and therefore higher over-wintering survival rates.

It has been shown that 2-8°C is the optimal temperature range for incubation (Tang et al 1987), which was the observed range in Scott River tributaries during most of the survey period. However, eggs incubated around 2°C will have a significantly longer incubation period than eggs incubated at 8°C. Studies of coho salmon in Washington State (Tang et al 1987) showed that eggs held at 2.5°C hatched in 162 days, while eggs held at 8.4°C hatches in 58 days. The observed 4°C difference in Mill Creek versus French and Sugar could lead to Mill Creek fish emerging in around ½ the time.

Population Estimates

Conditions were ideal for mark and recapture surveys during the 2004-2005 adult coho spawning period. High spawning activity in the mark and recapture reaches, as well as low flow during the survey period, led to relatively high mark and recapture rates. However, the relatively short window of spawning activity (4 weeks in Shackleford-Mill) resulted in few marked trials (ie. marked carcasses by stratified week) being out, increasing the error in the estimates. For future survey years, changing the mark and recapture schedule to semi-weekly should be considered.

The population estimate effort should be expanded in 2007-2008 to include reaches in Patterson, Etna, Kidder, South Fork, East Fork and Sugar Creek. The spawning period of 2007-2008 is selected, because it is the next cycle of this brood year. Returning spawner numbers are expected to be sufficient to complete mark and recapture studies. However, given the consistent spawner return in Shackleford-Mill Creek (present in all three brood years), population estimates could be attempted in each survey season.

Other Observations

During the survey period flow conditions were relatively stable, and overall fairly low. The USGS gauge was less than 500 cfs for much of the spawning period. It was observed in the lower alluvial reaches (Lower Patterson, Lower Shackleford, Middle French and Miners Creek), that during periods of extremely low temperatures flows dropped enough to lead to potential dewatering and surface freezing of side channels. It is unknown what affect this will have on survival of the eggs buried in the redds.

Flow conditions vary from year to year, and the potential dewatering of redds might not be an issue in other water years.

Recommendations

Based on the surveys completed during the 2004-2005 coho season, the following recommendations are made:

Future Adult Coho Spawning Ground Surveys.

Survey efforts should be closely coordinated with the Fall Chinook survey crews, to determine when coho first enter the Scott River. Maintenance of a proposed video weir at Young's Dam will help determine when coho first enter the upper Scott Valley, and provide a count for fish utilizing this section of the valley (Scott River RM 47 – 56, French Creek, Sugar Creek, East and South Fork, Wildcat Creek).

The following reaches should be established/retained as permanent index reaches: Lower Masterson, Lower Sugar, Middle French, Middle Patterson, Lower Shackleford, Lower Mill. These reaches are selected based on the high quality of habitat available for spawning. These reaches would be especially valuable during the two heavily impacted brood years coming up, as fish would be expected to utilize the best habitat available.

Additional effort should be made to document the full distribution of spawning in Kidder Creek, and the East Fork Scott River. After that point in time an index reach for Kidder Creek and the East Fork should be established. An index reach should also be established on the South Fork. However, effort should be made to acquire more access in the lower two miles of the South Fork.

Summer Habitat Utilization Surveys – Summer 2005

It is recommended that summer habitat utilization surveys be completed in all streams surveyed during the 2004/2005 adult coho surveys. Attempts should be made to survey as many representative reaches as possible, with the following being the highest priority; Lower East Fork, Upper and Lower Sugar, Middle and Upper French, Middle and Lower Patterson, Lower Shackleford, Lower Mill, Upper Mill, Lower Scott Bar Mill and Lower Tompkins Creek. These reaches were selected based on the spawning observed, known habitat quality based on habitat typing, and an attempt to include reaches representative of the variety of habitats in the Scott River Basin.

Scott River Adult Coho Spawning Ground Survey Training
November 17th, 2004
Siskiyou RCD Office
Etna

9:30	Meet at RCD office
	Introductions
	Purpose/Objectives
	Data Sheets/maps
	Carcass Tagging
	Sample disposition
10:30	Split into groups for the following sessions:
	Fish ID and tissue and scale collection - Mark Pisano(CDFG) and Erich Yokel (RCD)
	GPS data collection/naming conventions - Danielle Quigley
11:30	Meet back together
	Sign up sheets with contact information
	Pass out survey Kits and notebooks
11:45	Break for lunch
12:30	Short field survey (for those needing it)

Scott River Adult Coho Surveys 2004-2005

Project Objectives:

1) Document the presence of coho salmon in streams within the historic range of distribution and in new tributaries not previously documented within the Scott River system. Survey "index reaches", as delineated in the 2001-2002 survey, once per week once the spawning begins (December 1, 2002-January 31, 2003), or as determined by run timing.

2) Document the extent of coho spawning distribution in each of the tributaries where adult coho salmon were observed.

3) Determine the run timing and duration of adult coho salmon spawning in the Scott River.

4) Collect two sets of tissue samples for DNA analysis to understand the genetic relationship of the Scott River coho salmon to other stocks and collect two sets of scale samples to understand the life history of the Scott River coho salmon. One set of tissue and scale samples will go to NOAA Fisheries and one to CDFG.

5) Determine additional site specific information as they relate to spawning: velocity, substrate composition, temperature and stream gradient.

Redd Identification and Marking

Redd identification will follow the standard identification process used during the Fall Chinook salmon surveys. Redds will be counted if they are nearly completed and if there is an **80%** confidence by the surveyor that it is a redd. Redds with coho salmon on them are counted as "**Redds with Fish**" and distinguished from "**Redds without Fish**" in the field notes.

Redd Identification

The redd is the "nest" where the eggs have been deposited. The female coho salmon constructs her redd similarly to that of other salmonids. She selects an appropriate site, usually with the right size of gravel (generally 1/2"-4" diameter), depth and velocity of water (1-3 fps), then begins by digging a depression (pott) and depositing some of her eggs while the male fertilizes them. She then moves slightly upstream, digging another depression and at the same time backfilling and covering the eggs she has deposited. The eggs are buried in the cleaned gravel several inches to a foot or more deep. Over the course of several days, the female continues to deposit her eggs, working in an upstream direction. When the redd is completed it looks like a tear-dropped shaped mound of gravel extending downstream, approximately 4-5 feet long and 2-3 feet wide, below the last excavation, or pott (approx. 3-8 inches deep). The gravels are generally uniform in size and are often very shiny from recently being moved.

Flagging the Redd
Redds will be marked with hot pink flagging hung on the bank opposite the head of the pott of each redd to prevent duplicate counting on subsequent passes. The flag will be labeled with:

- ♦ date
- ♦ site code
- ♦ surveyors initials.

Data collection
The following information will be recorded on the data sheets; Length and width of the redd, depth of the pott, and dominant substrate composition

Location by GPS
Hand-held Global Positioning System (GPS) units will used when possible to record the location electronically (waypoint) of each carcass, redd or live fish. GPS waypoints will labeled with a stream code, sequential number and a single letter code, denoting carcass (C), redd (R), or fish (F), as well as the beginning and end of each reach surveyed (B or E). Other sites were noted with an (S), for "special".

Ex.: S F K 0 7 R = South Fork #7 Redd

All GPS units will set prior to the survey using Datum WGS 84 and coordinates in Lat/Long (h.ddd°mm.mmm). In addition, all sightings should also be field mapped.

Fish Identification (See Fish ID Sheet)
Morphological variation present in both coho and chinook requires utilizing a suite of characteristics to confirm the identity of coho salmon.. The following characteristics can be used:

Size – coho salmon adults are generally smaller than Chinook.

Gums - White gums at the base of the teeth have been acknowledged as the most reliable characteristic for identification of coho.

Spots - These are black in color and can vary from circular spots to irregularly shaped spots and are generally small in size.

Color - Coho salmon, both male and female, can exhibit extremely brilliant pink to red coloration over the lower 2/3rds of the body. In contrast, most chinook exhibit olive to red coloration and usually only in males.

Kype - Both males and females have a fairly pronounce kype, with the male being larger and more hooked than the female. In chinook only the male has a kype and it is much less pronounced than coho.

Nares -Nares are enlarged and white in coloration.

Anal fin – The lowest rays of anal fin of coho salmon are nearly as long as the upper rays. Fold the anal fin over to line up the lower rays with the upper rays.

Caudal Peduncle - The caudal peduncle of a coho is generally thicker than that of a chinook. It will be noticeable when picking up the carcass as it is difficult to grip the coho by the peduncle.

Sex - Males are identified by their larger more hooked kype, brilliant pink to red coloration and larger size.
Females are identified by their smaller kype, slightly duller coloration and smaller body size.
Jacks (2 yr. old males) are distinguished from other males and females by their smaller size (<40cm).
Additionally, if there is doubt on the sex of a carcass the anal opening can be squeezed to determine the presence of milt, which indicates a male. In, addition, the carcass can be opened up with a knife in order to view the egg skeins (female) or milt sacs (male).

Origin – Hatchery fish are identified by either the lack of an adipose fin or by a maxillary clip (right indicating Trinity River Hatchery and left indicating Irongate Hatchery). **For adipose clipped fish the head will sampled (cut off with a knife) to determine the hatchery origin by coded-wire tag.**

Scott River Watershed Adult Coho Salmon Spawning Survey 2004-2005
GPS Codes for Streams

Datum for all Garmin GPS units should be set at WGS84, and Projection in Lat/Long Decimal Degrees
